Mill examines the concept of justice in chapter 5 of *Utilitarianism*. Having observed that the idea of something which one may be constrained or compelled to do, on pain of penalty, is central to the idea of an obligation of justice, he notes that it nevertheless 'contains, as yet, nothing to distinguish that obligation from moral obligation in general':

> The idea of penal sanction, which is the essence of law, enters not only into the conception of injustice, but into that of any kind of wrong. We do not call anything wrong, unless we mean to imply that a person ought to be punished in some way or other for doing it; if not by law, by the opinion of his fellow creatures; if not by opinion, by the reproaches of his own conscience.
>
> (1865b: 246)

This is a normative, not a positive, account of morality: the morally wrong is that which *ought* to be punished, by law, social opinion or conscience. It would be a circular account if the 'ought' in question were itself a moral 'ought'. But the utility principle is the ultimate principle of 'Teleology'. Teleology is the 'Doctrine of Ends'; 'borrowing the language of the German metaphysicians', Mill also describes it as 'the principles of Practical Reason' (1843: 949-50). So the 'ought' is the 'ought' of Practical Reason - which, making appropriate use of 'laws of nature', produces the 'Art of Life'. Morality itself is only one department of this art. Moral concepts and judgments issue from the moral sentiments, the sentiments involved in guilt and blame; but are corrigible by a rational doctrine of ends. And that doctrine, in Mill's view, is the utility principle.

From this account of morality Mill moves to an account of rights and justice. A person has a moral right to a thing if there is a moral obligation on society to protect them in their possession of that thing. Obligations of justice are distinguished from moral obligations in general by the existence of corresponding rights:

> Justice implies something which it is not only right to do, and wrong not to do, but which some individual person can claim from us as his moral right…. Whenever there is a right, the case is one of justice.
>
> (1865b: 247)

Upholding rights is one of society's vital tasks. For on it depends our security - which is 'to every one's feelings the most vital of interests':

> This most indispensable of all necessaries, after physical nutriment, cannot be had, unless the machinery for providing it is kept unintermittedly in active play. Our notion, therefore, of the claim we have on our fellow-creatures to join in making safe for us the very groundwork of our existence, gathers feelings around it so much more intense than those concerned in any of the more common cases of utility, that the difference in degree (as is often the case in psychology) becomes a real difference in kind.
>
> (1865b: 251)

In this way the claim of justice comes to be felt as a claim of a higher kind than any claim of utility. Justice, Mill concludes,

> is a name for certain classes of moral rules, which concern the essentials of human well-being more nearly, and are therefore of more absolute obligation, than any other rules for the guidance of life.
>
> (1865b: 255)

Mill spells out in detail what these moral rules should be in his writings on various social questions. In *Utilitarianism*, he is concerned with the more abstract task of showing how justice-rights take priority over the direct pursuit of general utility by individuals or the state, just as they take priority over the private pursuit of personal ends. His position is thus more complex than that of philosophers in a Kantian tradition who assume, in John Rawls' phrase, that the right (or just) is prior to the good. For Mill, good is philosophically prior to right - but politically and socially right constrains the pursuit of good (see Justice §3).

12 Liberty and democracy

The most celebrated part of Mill's social philosophy, his essay *On Liberty*, must be read in terms of this conception of the right and the good. Mill is not a social contract or 'natural rights' liberal. He appeals instead to 'utility in the largest sense, grounded on the permanent interests of man as a progressive being' (1859: 224). He has in mind the higher human nature, capable of development by self-culture, which he believes to be present in every human being. Self-culture opens access to higher forms of human happiness, but it has to be *self*-culture, first because human potentialities are diverse and best known to each human being itself, and second because only when human beings work to their own plans of life do they develop moral freedom, itself indispensable to a higher human nature.

Given the importance free self-culture thus assumes in Mill's idea of human good, and the account of rights which has just been considered, it will follow that individual liberty must be a politically fundamental right. For self-development is one of 'the essentials of human well-being'. Thus Mill is led to the famous principle enunciated in *On Liberty*:

> the only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others. His own good, either physical or moral, is not a sufficient warrant. He cannot rightfully be compelled to do or forbear because it will be better for him to do so, because it will make him happier, because, in the opinion of others, to do so would be wise, or even right.
>
> (1859: 223-4)

A society which respects this principle enables individuals to realize their potential in their own way. It liberates a mature diversity of interest and feeling, and it nurtures the moral freedom of reason and will. Throwing open the gates to talent, creativity and dynamism, it produces the social conditions of moral and intellectual progress. This Millian argument remains the strongest defence of any liberalism founded on teleological ethics. It is a resource upon which teleological liberals will always be able to draw, whether or not they accept Mill's hedonistic conception of the human good or his aggregative conception of the good of all.

However, it is also connected with Mill's ambivalence about democracy. Like many other nineteenth-century thinkers, liberal as well as conservative, Mill felt a deep strain of anxiety about democratic institutions and the democratic spirit (see Democracy §2). Certainly he applauded the end of the *ancien régime* and sympathized with the moral ends of the French Revolution - liberty, equality, fraternity - but he learned from it, as had the continental liberals, to fear an enemy on the left, as well as an authoritarian enemy on the right. In its revolutionary form the enemy on the left threatened Jacobin terror, or the disasters which attend any attempt to achieve moral ideals by restarting history at year zero. Its settled form, on the other hand, could be observed in the 'democratic republic' of America: a continuous and unremitting pressure towards conforming mediocrity.

The Romantic-Hellenic ideal of human life both inspired Mill's democratic ideals and fuelled his fears about realized democracy. It was an ideal he shared with left Hegelians like Marx, who experienced less difficulty in combining it with democratic egalitarianism. Mill too had a long-term vision in which the emancipation and education of the working class could bring free self-culture to all human beings. He was able to believe, on the basis of his associationist psychology, that all human beings have an equal potential to develop their higher faculties. This warded off the possibility that utilitarianism might recommend an extremely inegalitarian pursuit of higher forms of well-being as the equilibrium state of a fully-developed human society.

Thus Mill remained more of a democrat than other liberals of the nineteenth century, such as de Tocqueville or Burckhardt, but like them he saw how moral and cultural excellence and freedom of spirit could be endangered by mass democracy. Like them, his attitude to the immediate prospect of democratic politics was decidedly mixed.

What he wanted was a democratic society of freely developed human beings; he did not think it a proximate or certain prospect, and he thought that bad forms of democracy could themselves pose a threat to it by drifting into ‘collective despotism’ - a danger to which America had already succumbed.

His advice for warding off this threat was not less democracy but more liberty:

> If the American form of democracy overtakes us first, the majority will no more relax their despotism than a single despot would. But our only chance is to come forward as Liberals, carrying out the Democratic idea, not as Conservatives, resisting it.
>
> (1972: 672)

This was the importance of the essay on Liberty, and particularly of the defence of liberty of thought and discussion contained therein. Nor were freedom of speech and liberty of the individual the only instruments by which Mill hoped to steer away from bad forms of democracy towards good. Some of his recommendations - plural voting, a public ballot, a franchise restricted by educational qualification - may now seem misguided or even quaint. Others, including proportional representation of minorities and, not least, his life-long advocacy of equal rights for women, make him seem ahead of his time. At any rate, in political philosophy from Plato’s *Republic* to the present day, Mill’s discussion of democracy has few rivals - for its open-mindedness, its historical and psychological awareness, and its underlying ethical power.

JOHN SKORUPSKI

List of works

Mill, J.S. (1991) *Collected Works of John Stuart Mill*, ed. J.M. Robson, London: Routledge and Toronto, Ont.: University of Toronto Press.(The standard edition of Mill’s writings, in thirty-three volumes. The introductions are invariably worth reading. Volume and page numbers given below refer to this edition.)

Mill, J.S. (1838) *Bentham*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 10, 75-115, 1991. (Mill’s radical assessment of Bentham, usually read in conjunction with the essay on Coleridge.)

Mill, J.S. (1840) *Coleridge*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 10, 117-63, 1991. (These two essays most accessibly illustrate how Mill wove together Enlightenment and Romanticism.)

Mill, J.S. (1843) *System of Logic: Ratiocinative and Inductive*, in *Collected Works of John Stuart Mill*, London: Routledge, vols 7 and 8, 1991.(The nineteenth century’s most penetrating exposition of a naturalistic philosophy of logic and science, including social science. The pagination of volumes 7 and 8 is consecutive; volume 8 begins at page 639.)

Mill, J.S. (1848) *Principles of Political Economy*, in *Collected Works of John Stuart Mill*, London: Routledge, vols 2 and 3, 1991.(A synthesis of classical economics, this work also contains much interesting social philosophy.)

Mill, J.S. (1859) *On Liberty*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 18, 213-310, 1991. (One of liberalism’s canonical texts.)

Mill, J.S. (1861a) *Utilitarianism*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 10, 203-59, 1991.(A central text of moral philosophy - its extraordinary succinctness means that much in it remains to be fully charted and quarried.)

Mill, J.S. (1861b) *Considerations on Representative Government*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 29, 371-577, 1991.(One-man report on the prospects of democracy.)

Mill, J.S. (1865a) *An Examination of Sir William Hamilton’s Philosophy*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 9, 1991.(Mill’s main treatment of metaphysical issues, including the nature of mind and matter, free will, logic and thought.)

Mill, J.S. (1865b) *Auguste Comte and Positivism*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 10, 261-368, 1991.(An assessment, from Mill’s later years, of a philosopher who greatly influenced him in his youth.)

Mill, J.S. (1869) *The Subjection of Women*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 21, 259-340, 1991.(Manifesto of nineteenth-century liberal feminism.)

Mill, J.S. (1873) *Autobiography*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 1, 1-290, 1991.

(Famous account of Mill's early education, 'mental crisis', and subsequent intellectual and moral projects.)
Mill, J.S. (1874) *Three Essays on Religion*, in *Collected Works of John Stuart Mill*, London: Routledge, vol. 10, 369-489, 1991.(Posthumously published articles, in which Mill argues that religious hope is legitimate, whereas religious belief is not.)
Mill, J.S. (1879) *Chapters on Socialism*, in *Collected Works of John Stuart Mill* , London: Routledge, vol. 5, 703-53, 1991.(Posthumously published assessment of socialism which complements the *Principles of Political Economy* and *On Liberty*.)
Mill, J.S. (1972) *Later Letters*, in *Collected Works of John Stuart Mill*, London: Routledge, vols 14-17, 1991. (Mill's extensive correspondence after 1848, published in four volumes.)

Millar, John (1735-1801)

John Millar elevated law teaching from mere instruction in technicalities to the level of a genuinely liberal subject, largely by using his teaching to educate students in the science of legislation. A pupil and disciple of Adam Smith, Millar, through his teaching and writing, established his reputation as a key figure in the Scottish Enlightenment movement.

Millar was born on 22 June 1735, a son of the manse of Kirk o'Shotts in Lanarkshire, just as the first signs of 'the great awakening' in Scotland were materializing. He entered Glasgow University in 1746, leaving in 1752 to pursue a legal career. In 1761, at the age of 26, Millar was elected to the Regius Chair of Civil Law in Glasgow and there he taught until his death in 1801.

He was not a prolific writer. There are only two works which can definitively be attributed to him. The first, *The Origin of the Distinction of Ranks* (1771), is the book on which his reputation primarily rests. In *Ranks* Millar broke away from a traditional cyclical view of progress in which the conduct of politics was rooted in a dialectic between virtue and corruption, and presented the development of civil society as a process of unilinear advance. Millar's account constitutes a succinct statement of historical materialism: there are four stages - hunting, pasture, agriculture and commerce - through which societies pass and each form of economic organization gives rise to 'correspondent habits, dispositions and ways of thinking'. Millar argued that this was a natural progression - from ignorance to knowledge, from rude to civilized manners - and, though the general method was not novel, he seems to have been the first to have indicated the causes of growth through each of the sequential phases.

The other book, *An Historical View of the English Government* (1787), is a constitutional history from Saxon times to the Stuarts. Millar here utilizes the method employed in *Ranks*, mainly to challenge the vulgar Whiggism of writers such as William Blackstone who tended to view English constitutional history in terms of a gradual restoration of the ancient Anglo-Saxon constitution which had been undermined by the Normans. Millar, presenting a 'scientific Whig' account, argued that the 'low ranks' secured their liberty not by appeals to a romantic idea of the ancient constitution and not by pieces of paper but by industry and material progress. The origin of liberty in Britain is modern, not ancient; it was a seventeenth-century endeavour culminating in 1688.

Millar's general theoretical approach was historical and sociological rather than conceptual. He rejected any idea that law is determined by higher norms of divine origin or theories of law rooted in social contract. In this sense, he adopted a modern, sociological view that any theory of law must be rooted in a theory of society. Assessments of Millar's originality vary, but it is undoubtedly the case that he made a significant contribution to a remarkable period of, not only Scottish, but European intellectual history.

Mīmāṃsā

The school of Mīmāṃsā or Pūrva Mīmāṃsā was one of the six systems of classical Hindu philosophy. It grew out of the Indian science of exegesis and was primarily concerned with defending the way of life defined by the ancient scripture of Hinduism, the Veda. Its most important exponents, Śabarasvāmin, Prabhākara and Kumārila, lived in the sixth and seventh centuries AD. *It was realist and empiricist in orientation. Its central doctrine was that the Veda is the sole means of knowledge of* dharma *or righteousness, because it is eternal. All cognition, it held, is valid unless its cause is defective. The Veda being without any fallible author, human or divine, the cognitions to which it gives rise must be true. The Veda must be authorless because there is no recollection of an author or any other evidence of its having been composed; we only observe that it has been handed down from generation to generation. Mīmāṃsā thinkers also defended various metaphysical ideas implied by the Veda - in particular, the reality of the physical world and the immortality of the soul. However, they denied the existence of God as creator of the world and author of scripture. The eternality of the Veda implies the eternality of language in general. Words and the letters that constitute them are eternal and ubiquitous; it is only their particular manifestations, caused by articulations of the vocal organs, that are restricted to certain times and places. The meanings of words, being universals, are eternal as well. Finally, the relation between word and meaning is also eternal. Every word has an inherent capacity to indicate its meaning. Words could not be expressive of certain meanings as a result of artificial conventions.*

The basic orientation of Mīmāṃsā was pragmatic and anti-mystical. It believed that happiness and salvation result just from carrying out the prescriptions of the Veda, not from the practice of yoga or insight into the One. It criticized particularly sharply other scriptural traditions (Buddhism and Jainism) that claimed to have originated from omniscient preceptors.

1 History

Mīmāṃsā, one of the six systems (*darśanas*) of Hindu philosophy, was not originally a system of philosophy at all but an auxiliary of Vedic study (see Hindu philosophy §§6-7). Mīmāṃsā literally means 'investigation' or 'analysis'; it refers specifically to the analytic discussion of Vedic ritual. (The Veda is the most ancient scripture of the Hindus.) The *Mīmāṃsāsūtra*, the earliest treatise of the school, which is attributed to Jaimini and dated around the second century BC, is a compendium of debates about how rituals should be carried out; it resolves the debates by carefully analysing the language of the scriptural passages in which the rituals are enjoined. Thus, the school of Mīmāṃsā was first and foremost concerned with exegesis. It developed a system of rules of interpretation that were widely employed elsewhere in Indian philosophical and scientific literature; they were especially used in interpreting and expounding the Dharmaśāstras, works relating to Hindu ethics and law.

At an early stage, Mīmāṃsā took on the broader role of defending Hindu *dharma* as a whole. *Dharma* means what one ought to do and avoid doing, the proper way to conduct oneself in this world and to attain salvation in the next. It includes not just the carrying out of certain rituals but also the observance of the minute details of everyday custom and etiquette. The Brahmanical or priestly conception of *dharma*, which was central to the culture that called itself 'Aryan' in ancient India and which became the core of classical Hinduism, was attacked by various heterodox movements, especially Buddhism and Jainism, from around the fifth century BC. Mīmāṃsā undertook to defend the Brahmanical system by attempting to demonstrate, in particular, the sole authority of the Veda with regard to matters of religion and ethics, and the falsehood of other scriptures. This apologetic enterprise led into the consideration of various philosophical issues, including metaphysical doctrines implied by the Veda and epistemological and linguistic doctrines upon which the claim of the authority of the Veda was based.

As in the case of the other Hindu philosophical systems, Mīmāṃsā was expounded chiefly in commentaries and subcommentaries on a foundational *sūtra* text (a treatise in the form of short statements or aphorisms), namely the *Mīmāṃsāsūtra*. The *Mīmāṃsāsūtra* originally contained material relating both to the interpretation of the ritual portions of the Veda and to the mystical-philosophical texts known as the Upaniṣads. The *sūtras* relating to the latter, however, were at an early date separated off and, known as the Vedānta or *Brahmasūtra*, became the focus of a distinct tradition of philosophical reflection, namely Vedānta. The oldest existing commentary on the Pūrva or 'prior' *Mīmāṃsāsūtra* - the *sūtras* concerned with ritual - is that of Śabarasvāmin, the *Śābarabhāṣya*, dated around

the sixth century AD. Other, older commentaries, such as that of Upavarṣa, have not been preserved. Two principal subschools of Mīmāṃsā thought, the Bhāṭṭa and the Prābhākara, are based on subcommentaries on the *Śābarabhāṣya* by Kumārila (also known as Kumārilabhaṭṭa) and Prabhākara respectively. A trio of commentaries by Kumārila, the *Ślokavārttika*, *Tantravārttika* and *Ṭupṭīkā*, have been preserved; Prabhākara's commentary is titled the *Bṛhatī*. Both authors may be assigned to the seventh century. Another great figure of the early period was Maṇḍanamiśra, who was sympathetic to the views of Kumārila but also composed works on Advaita Vedānta. Other important figures of the Bhāṭṭa school were Umbekabhaṭṭa (eighth century), Pārthasārathimiśra (tenth century), Sucaritamiśra (tenth century), Someśvarabhaṭṭa (twelfth century) and Khaṇḍadeva (seventeenth century). The principal exponent of the Prābhākara school after Prabhākara himself was Śālikanāthamiśra (ninth century). A third school of Mīmāṃsā, which, unlike the other two, accepted the existence of God - the so-called Seśvara Mīmāṃsā- was established by Murārimiśra in about the eleventh century. The following exposition is based primarily on the teachings of the more influential Bhāṭṭa school, although occasional references will be made to distinctive Prābhākara positions.

2 Knowledge and reality

The Mīmāṃsāclaim of the sole authority of the Veda with regard to *dharma* is based on two highly controversial doctrines: the eternality of the Veda and the intrinsic validity of cognitions. According to Mīmāṃsā, any error in cognition derives from defects in the causes of the cognition. A conch shell, which is in fact white, appears yellow to someone whose eye is affected by jaundice; a notion derived from verbal testimony can be false if the witness is dishonest or incompetent. On the other hand, a cognition whose causes are not defective will necessarily be true. Thus, cognitions arising from the Veda must be true, because the Veda is eternal - it was never composed by anyone but has just been handed down from time immemorial, from generation to generation - hence they cannot have a defective cause. They are not in any way contingent on the knowledge and honesty of a fallible author.

Kumārila developed the theory of 'intrinsic validity' (*svataḥ prāmāṇya*) as a general epistemological theory. *All* cognitions, he argued, present themselves initially as true; they arise together with a sense of conviction that matters really are as they indicate. Cognitions are deemed false only when they are directly overturned by other cognitions or undermined by the discovery that their causes are defective. Cognitions of Vedic injunctions, indeed, are never effectively contradicted by other means of knowledge such as perception, inference or testimony, and, as stated, there can be no suspicion that their source is defective, for the Veda is eternal. Prabhākara held not just that all cognitions initially *appear* true but that all cognitions, strictly speaking, *are* true; there is no such thing as error. Every cognition apprehends something real. It is only our judgments, which combine cognitions together, that are mistaken. If I think 'This conch shell is yellow', I am not in fact misperceiving anything. I correctly perceive the conch as 'this', and I correctly perceive the yellow colour, which is due to the jaundice afflicting my eye. It is only the attribution of the yellow to the conch instead of my eye that is wrong. The theory of intrinsic validity evoked a violent reaction from other Hindu, Buddhist and Jaina philosophers, who argued that a cognition can be considered valid only when it is confirmed by another cognition, in particular, a cognition of the 'causal efficacy' (*arthakriyā*) of the object (see Epistemology, Indian schools of §3).

The Mīmāṃsā theory of intrinsic validity was conducive to the adoption of realist positions on a variety of metaphysical issues. Kumārila, along with most other Hindu thinkers, rejected the idealism of the Yogācāra school of Buddhism (see Buddhism, Yogācāra school of §§2-4). His principal argument for realism was simply that the perception of the world as comprising externally existing, physical objects must be considered valid unless and until it is contradicted by other perceptions, in the way dreaming is contradicted by waking consciousness. He also charged that the Buddhist view of experience as comprising self-luminous moments of consciousness - that is, cognitions that reveal, not external objects, but their own inherent forms - violates the principle that the same thing cannot function as both agent and object in the same act (in this case, an act of cognition). More crucially, Kumārila held that we are not aware of cognitions (*jñāna*) at all in experience; we do not, at the time we perceive an object, also perceive a cognition. Our awareness, rather, is completely absorbed in being aware of the object. Hence, there is no basis for suggesting that object and cognition are the same thing, for they never occur together. Kumārila, then, was a direct realist. He believed that we only infer the existence of a cognition (*jñāna*) as the cause of the fact that we have become aware of an external object.

The Prābhākara school, on the other hand, held, like the Buddhists, that consciousness (*saṃvitti*) is self-luminous;

it simultaneously reveals the object, itself, and the knower. Yet it reveals itself always as the conscious principle, never as the object, hence, contrary to the Buddhist teaching, experience itself shows us that object and consciousness are distinct. At the same time, 'cognition' (*jñāna*), in the sense of the act of mind which produces consciousness, is only inferred.

Not only does perception reveal an external world, it reveals its nature. The cognitions we have of objects as endowed with certain properties and being of certain types - as a white man, a walking cow, and so on - are true unless and until overturned by other cognitions. Moreover, such cognitions are perceptual and can be referred to as 'conceptualized perceptions' (*savikalpaka pratyakṣa*); they are caused by the contact of our sense organs with objects, though they are preceded by a moment of nonconceptualized perception (*nirvikalpaka pratyakṣa*) in which the various features of the object are not identified as particular *types* of features or named. Buddhist philosophers, on the other hand, held that conceptualized cognition is not perceptual but mainly involves an act of the imagination by which mentally constructed properties are projected onto things; it is a kind of illusion. Kumārila argued - once again appealing to the principle of intrinsic validity - that the enduring validity of most of our cognitions of objects as qualified by qualities, actions, universals, and so on suggests that in general they are not errors; if they were, they would always be overturned. The specific Buddhist charge that a conceptualized cognition involves the superimposition of a mere *word* upon the object is rejected on the grounds that in fact we first see what a thing is before we apply a word to it. The world is perceived as it is prior to language, and we speak about it in a certain way because of the way we perceive it.

The above teaching implies an acceptance of the reality of universals. Mīmāṃsā philosophers were at the forefront of the debate with the Buddhists over universals. While the Buddhists were nominalists, Hindu and Jaina philosophers held that universals must be posited to account for common notions and common terms, that is, the fact that we cognize various things as being of the same type and refer to them by the same word. Kumārila in particular developed trenchant criticisms of the Buddhist theory that common concepts are just mentally constructed 'exclusion classes', the so-called *apohavāda* (see Universals, Indian theories of §2). The Bhāṭṭa view of universals was somewhat different from that of other realist schools, however, in that it considered universal and particular to be different aspects of one thing and not entirely distinct; the same thing is universal from one angle, particular from another. (It developed a similar view of nonbeing, *abhāva*: a thing is both what it is and what it is not. When we judge that a pot is *not* a cloth, we are apprehending a real, negative aspect of the pot. This tendency of Bhāṭṭa thought is believed by some to reflect the influence of Jainism.) Kumārila criticized the Nyāya-Vaiśeṣika notion that universal and particular are externally related to each other by virtue of 'inherence' (*samavāya*) (see Nyāya-Vaiśeṣika §5). The Prābhākara school, meanwhile, adopted the more conventional stance that universals are distinct from the individuals in which they inhere, but it worked out a more felicitous theory of inherence.

Mīmāṃsā philosophers - again in concert with other Hindu thinkers and against the Buddhists - defended the existence of the soul. An immortal soul is clearly implied by Vedic injunctions of certain sacrifices for the attainment of heaven. Kumārila argued that the existence of an unchanging self is established by the fact that I recognize *myself* as the subject of remembered experiences, hence I must have existed continuously from the past to the present. He also held the self to be essentially self-conscious; the Prābhākara, on the other hand, held that the self becomes manifest only in empirical consciousness and has no consciousness of its own.

Although an apologist for Vedic tradition, the Mīmāṃsaka (Mīmāṃsā philosopher) rejected a supreme being as creator of the universe and author of the Veda. This accords with his staunch empiricism and his belief that the positing of any author of scripture, even a divine one, tends to call it into question. Kumārila extensively refuted the Nyāya arguments for the existence of God as creator. What could his purpose have been in creating the universe? Not the fulfilment of the past karma of living beings, because living beings did not then exist; not 'sport' or amusement, for that would imply some lack in God. Yet if he did it without desire or purpose, he could not be considered intelligent, for no intelligent person acts without a purpose. And so on. Kumārila even rejected the Hindu mythological idea of a periodic creation and destruction of the universe, asserting that we have no evidence that the world has ever been different from how it is now. References to gods in the Veda are not to be taken literally but just as eulogies that serve to recommend certain sacrifices. Heaven is just a region, whose location is indefinite, where one experiences 'pure happiness'. The soteriological goal of *mokṣa*, liberation from the cycle of rebirth, is negatively conceived, not as an experience of transcendental bliss but as the cessation of all

association with a body due to the exhaustion of karma (see Karma and rebirth, Indian conceptions of §§1-4). Thus, Mīmāṃsā is decidedly rationalistic in its interpretation of Vedic religion. The religious life, for Mīmāṃsā, consists not in the practice of yoga or the attainment of insight into the oneness of everything, but in the scrupulous observance of *dharma* as laid down in Vedic prohibitions and commandments.

3 Language and scripture

Mīmāṃsā insisted on the eternality of the Veda on the grounds that its composition has not been observed, nor is there any memory of its having been composed by anyone in the past. Rather, we observe simply that it has been transmitted from generation to generation. What sense, however, can there be in suggesting that there could be a discourse that was never composed by anyone? Language surely always expresses the thoughts of intelligent beings, and depends on the articulation, by living speakers and writers, of symbols that are conventionally linked with certain meanings. Precisely such a view of language is what Mīmāṃsā rejected; in its place, it defended the eternality (*nityatva*) of language in general.

Individual words themselves must be eternal, for we routinely recognize a word we use as ‘the same word’ we used before. We never utter new words but only the same ones over and over. Nor should it be thought that a word is perishable because it consists of momentarily heard sounds. Rather, articulated sounds (*dhvani*) serve only to evoke an awareness in the hearer of the eternal, ubiquitous word; they are not identical with the word itself. In particular, they are not its letters (*varṇa*) - Kumārila insisted, against the grammarian Bhartṛhari, that a word, though eternal, is not an indivisible entity (*sphoṭa*) but comprises a sequence of letters - for letters, too, are omnipresent and eternal. We also recognize a particular letter as ‘the same letter’ as before. It is cognized at a particular time and place due to an alteration in the ear brought about by a disturbance of the air caused by the vocal organs (see Language, Indian theories of §3). The meanings of words are also eternal, according to Mīmāṃsā, for they are universals.

But surely the conventions by which words are assigned certain meanings were fixed by intelligent beings at a certain time, in which case the Veda could not be altogether eternal? The Mīmāṃsaka denied even this; rather, he held that a word does not refer to its meaning by virtue of a convention but rather by an inherent capacity (*śakti*). Kumārila, in particular, argued that the connection of word and meaning cannot be a human construct. A uniform convention devised by humans could only be based on some underlying natural relationship, while diverse conventions observed by different users would render communication impossible. That uniform conventions were established by God at the beginning of time is precluded by doubts about the existence of God. Moreover, it would seem that the devising of conventions by anyone already presupposes the existence of language. Finally, in contrast to the custom with other conventional practices in ancient India, we do not recall the authors of particular conventions when we employ words. (The Mīmāṃsā school holds that in the performance of rituals, for example, we do always recall their authors.) All we observe, in fact, is that we learn what words mean from our elders, who in turn learned the meanings from their elders, and so on; we never observe anyone originally establishing the meanings of common words such as ‘cow’. The Mīmāṃsaka, of course, was cognizant of the fact that other cultures used different words for things, but he insisted that only Aryas speaking proper Sanskrit used the *correct* words! Others use words that do not really mean what they think they mean and whose expressiveness derives only from similarity to Sanskrit words. The fact that there is a natural connection between word and meaning does not entail that everyone must automatically know what a word means, either. Although the connection is natural, it still must be learned.

Nor, finally, is the meaning of a particular utterance dependent on the intention of the utterer. Mīmāṃsā rejected the view, propounded by both Buddhist philosophers and the Hindu Vaiśeṣika school, that verbal testimony is a form of inference, in the sense that we infer facts about the world from what a person says via the belief that what is said expresses the state of mind of the speaker. By contrast, Mīmāṃsā held that language of itself says things. We can, for example, understand what a sentence means without knowing who uttered it or whether that person is reliable or not. A speaker selects a certain pattern of words to express a thought just because those *words* already express a certain state of affairs. Bhāṭṭa and Prābhākara philosophers differed, however, on the matter of how the eternal meanings of individual words combine to form sentence meanings. The Bhāṭṭa view (the so-called *abhihitānvayavāda*) was that individual words first indicate their ‘own meanings’, which in turn combine into the sentence meaning; the Prābhākara view (the *anvitābhidhānavāda*) was that a word originally indicates a meaning

that is modified by the other words with which it stands in syntactic relation in the sentence. The latter theory implies that a word never means exactly the same thing in any two sentences.

Part and parcel of the Mīmāṃsā defence of the authority of the Veda was the effort to debunk other scriptures. The Buddhists and Jainas grounded the authority of their scriptures on the claim that they contained the utterances of omniscient beings - the Buddha and Mahāvīra respectively. Kumārila, in particular, ridiculed the idea of omniscience. We do not know of any omniscient people now, so on what basis should we believe that there were omniscient people in the past? Indeed, we observe that some people are smarter and more talented than others, but that hardly justifies believing in the existence of people who literally knew everything! Moreover, the statements of the Buddha and Mahāvīra, each claimed by his tradition to be omniscient, contradict each other. Given also the observation that humans for the most part say what is false, and that, especially when it comes to religion, charlatans abound, it is altogether safer to rely on a tradition that does not make outrageous claims about the omniscience of its founder, or, for that matter, appeal to any fallible human author at all. Indeed, humans cannot know what *dharma* is through their own faculties. For *dharma* is 'that which is conducive to the good', that is, the happiness of humans, and humans are incapable of knowing through their own faculties which actions yield happiness after death. For that reason, *dharma* is not to be based on rationally conceived, universal ethical principles such as nonviolence or 'benefiting others'. *Dharma* is just what the Veda tells us to do.

Mimēsis

A crucial term in the literary theories of Plato and Aristotle, mimēsis *describes the relation between the words of a literary work and the actions and events they recount. In Plato, the term usually means 'imitation' and suggests that poetry is derived from and inferior to reality; in Aristotle, it loses this pejorative connotation and tends to mean simply 'representation' and to indicate that the world presented in a poem is much like, but not identical with, our own.*

A relation of *mimēsis* to authoritative figures from the past - heroes, fathers, philosophers, authors - was deeply ingrained in ancient Greek and Roman culture, and laid the groundwork for the post-classical notions of the pedagogical value of antiquity as a whole that shaped the classical tradition. *Mimēsis* is usually translated 'imitation', but in fact its central meaning is closer to 'actualization': objects, events, or actions which, because they are divine, past or canonical, belong to a more valuable domain of reality than our quotidian lives but are therefore in some way remote from us, enjoin upon us the obligation to restore their actuality; this is achieved by establishing a privileged sector within our present concerns in which we can (re-)enact them, thereby illuminating our banal world with some of their splendour while rescuing them from the perils of abstraction and irrelevance. Hence the term *mimēsis* is intrinsically ambivalent and, depending upon the circumstances, can emphasize either the actualization's inferiority compared to its model or the relative superiority it acquires by its temporary participation in the model's prestige.

This cultural complex provides the context for Plato's introduction of *mimēsis* as a concept of philosophical aesthetics and literary theory. Three different levels of generalization can be distinguished in Plato's usage of the term in the *Republic* (seePlato §14). First, discussing poetry's content in Book II, he applies the term broadly to the relation of signification between utterances and the entities to which they refer. Then, moving on to poetry's form in Book III, he exploits the fact that in Greek tragedy ordinary human actors played the roles of legendary heroes and gods to invent the novel, highly specific application of *mimēsis* as a technical term to that whole literary genre, drama, in which authors never speak in their own voice, in contrast to the narrative, in which they always so speak, and to mixed forms. Finally, once he has established the tripartition of the soul in Book IV and the way in which lower levels of reality imitate higher ones (the divided line and the analogy of the cave in Books VI and VII) he can return in Book X more fundamentally and drastically to his critique of non-philosophical *mimēsis*; now all poetry, including non-dramatic forms, is deceptively mimetic, in the sense that it is at three removes from true reality. Unless a defender can be found to plead its case in prose, it must be exiled from Plato's ideal city.

In his *Poetics*, Aristotle accepts Plato's challenge (see Aristotle §29). Against *Republic* III he generalizes *mimēsis* beyond the criterion of the dramatic genre and against *Republic* X he empties it of any hint of inferiority with regard to an independent reality: instead, now all imaginative literature, including Plato's dialogues, is mimetic, in the sense that it describes not what really happened but the sort of thing that could happen. Aristotle's *Poetics* is a theory of the poet's making (*poiēsis*) of a representation (*mimēsis*) of characters' actions (*praxis*): in a tragedy, their *praxis* will turn out badly; in a good tragedy, the poet's *poiēsis* will turn out well. If the tragedian directly made actions, people would really commit and suffer outrages and we would be appalled; instead, by making a *mimēsis* of actions, the tragedian can represent them for our considered pleasure. *Mimēsis* is no longer the unique province of the deceived and deceiving artist, but instead an anthropological universal that distinguishes us from most other animals (as in fact imitation does) and provides specifically cognitive pleasures to all humans: we enjoy recognizing what we already knew and saying that 'this man' (whom we see before us) is 'that man' (of whom we had always heard).

Greek aesthetics never comes closer to the modern concept of fictionality than it does in Aristotle's universally generalizing, thoroughly non-derogatory use of the term *mimēsis*. Yet Aristotle, who never analyses the term, remains committed to the view that the world portrayed by poetry is not a fictional world, but a recognizable version of our own real one: poetry does not show us what actually happens or happened, but it does show us the kinds of things that could have happened and might happen. *Mimēsis* prevents the poet's *poiēsis* from making a real *praxis*; but the possibilities it describes are real, not fictional, ones. That is precisely why Aristotle can insist

upon a limited cognitive component in aesthetic pleasure.

Mind, bundle theory of

This theory owes its name to Hume, who described the self or person (which he assumed to be the mind) as 'nothing but a bundle or collection of different perceptions, which succeed each other with an inconceivable rapidity, and are in a perpetual flux and movement' (A Treatise of Human Nature I, IV, §VI). The theory begins by denying Descartes's Second Meditation view that experiences belong to an immaterial soul; its distinguishing feature is its attempt to account for the unity of a single mind by employing only relations among the experiences themselves rather than their attribution to an independently persisting subject. The usual objection to the bundle theory is that no relations adequate to the task can be found. But empirical work suggests that the task itself may be illusory.

Many bundle theorists follow Hume in taking their topic to be personal identity. But the theory can be disentangled from this additional burden.

1 Origins and nature of the theory

Hume's bundle theory originated in his response to what he took to be a natural illusion about personal identity:

> [S]ome philosophers…imagine we are every moment intimately conscious of what we call our SELF; that we feel its existence and its continuance in existence; and are certain, beyond the evidence of a demonstration, both of its perfect identity and simplicity.
>
> (*A Treatise of Human Nature* I, IV, §VI)

He thought that if that were so, the self would be an item within one's experience. But the self is not such an item: rather, it is that to which our experiences are ascribed. Neither can the existence of the self be inferred from, or found in any other way in, experience. If I introspect, all I find are thoughts, sensations, emotions, not the thing which has them.

This Cartesian self, then, is a myth. But how did the myth arise? Hume's own answer was that relations of resemblance and causation among one's different experiences lead one to suppose, mistakenly, that there is some real underlying unity. (A rough analogy would be getting the impression, in darkness, of a single light's travelling, by seeing adjacent lamps successively illuminated, each going on as its neighbour is extinguished.) This should not be interpreted as his offering some set of conditions for the truth of statements of the form '*x* is the same person as *y*'. Hume regarded it as his job not to give an account of personal identity, but merely to explain how we come to have the notion at all. But subsequent philosophers have conceived the bundle theory as just such an account.

One thing Hume's explanation of the origin of the notion of personal identity lacked was an answer to this question: given that there *are* bundles which constitute particular minds, what is it that ties a particular set of experiences into *that* bundle? Something must do so, because according to Hume, one gets one's false ideas about real identity by being presented with a limited set of experiences *already bundled* (not with all the experiences that there are, for most belong to other people). A Cartesian ego would do the job; but that is already condemned. And it would anyway not do a further job: lying as it does beyond the reach of experience, it would not on its own give one the notion of one's own self. Kant noticed this difficulty (*Critique of Pure Reason*, A103-10), and is sometimes read (for example by Strawson 1966: 163) as suggesting that a necessary element of the linking principle was the possibility of regarding one's experiences as *of* objects independent of those experiences, objects which provide the possibility of experiences which are not one's own (see Kant, I. §6). Be this as it may, bundle theorists have always been exercised by the need to provide suitable unifying links among experiences. Such links have to be capable of accounting for the unity of a single person, both at one time (synchronic unity) and across time (diachronic unity).

Hume's assumption of the identity of self and mind exacerbates his problem. For it multiplies the demands that a bundle theory has to meet. And defenders of the bundle theory have usually been those who have *argued* for this identity, so that they regard themselves as facing the task described of supplying links among experiences adequate to account for both the synchronic and diachronic unity of a person. But it is in principle possible for a bundle theorist of mind to hold, for example, a body-based account of personal identity (see Personal identity). Certain natural objections to the theory would then immediately collapse. One such is this: it seems obviously true

that I might have had a quite different set of experiences from the set I have had. But if I just *am* a set of experiences, this ’obvious truth’ must in fact be false.

Treating the bundle theory, then, as purely a theory of the nature of mind, what sort of theory is it? Initially, little more than a denial of the necessity of an immaterial owner of experiences, the bundle theory is almost defined by its claiming there to be no item in the category of mental substance to which experiences must be attributed. But it is also committed to the denial of the necessity for a material owner. The theory’s most natural form would thus be something like Russell’s post-1919 neutral monism (see Russell, B.A.W. §13; Neutral Monism). But it is compatible with versions of dualism and physicalism that do not have the strong ownership commitments just described. In this sense the bundle theory is only a partial account of the nature of mind.

2 Objections and replies

A common objection is that experiences are identity-dependent on their owners, that the only way in which a particular experience can be identified is as an experience of some person, and that the bundle theory is committed to denying this. But a bundle theorist could without inconsistency admit the claim of identity-dependence, and still ask for proof that the necessary owner must be something other than the rest of the bundle; only this further step would actually refute the theory.

Another, related, objection is that the theory has the supposedly absurd implication that experiences can exist in isolation from each other, for a bundle consists of things that can exist outside the bundle, and can in principle fall apart. If they cannot so exist, then Hume’s atomist version of the theory, where the experiences are mutually independent, would be false. But a non-atomist version of the theory, where the experiences are inextricably interlinked, such as one might find in William James’ neutral monism, could survive this objection (see James, W. §2).

More difficult is the problem of unity - finding suitable candidates for the cross-experiential links. Hume’s suggestions, resemblance and causation, seem more suited to solving the problem of diachronic rather than synchronic unity. But, jointly or severally, these are neither necessary nor sufficient for either. There is more resemblance among different people’s experiences of one thing than among one person’s experiences of different things; and experiences in one mind may have no causal relations between them (for example I hear the doorbell while watching television), whereas experiences in two minds might be cause and effect (for example if telepathy is possible).

Another possibility is that certain experiences embrace others. Synchronic unity would have to be guaranteed by something like a second-order awareness of co-presentation of several first-order experiences. But it is hard to see that such second-order awareness is always present, while its mere possibility seems itself to require explanation in terms of a single mind. (A possible response to this criticism would be that there is no such requirement, that we have reached bedrock.) Further, it would still leave the problem of diachronic unity, which needs another kind of embracing, for example memory’s spanning a sequence of experiences. This, on the face of it, would imply that an experience I do not remember belonged to a different mind. Again, the appeal to possibility seems no help.

Some bundle theorists have postulated diachronic links of a more sophisticated kind: if there is enough psychological connectedness over time, then there is a single mind. Connectedness is exemplified by recall of a previous experience, by the carrying out of a prior intention, or by the persistence of personality traits. It is a matter of degree, and hence can approach zero over the career of a single mind. It thus needs supplementation with psychological continuity, which is the holding of overlapping chains of a high degree of connectedness. But even together these links would allow a single mind to divide, with each successor having an equal claim to be the original, yet their diversity defeating that claim via the logic of identity. (If $b \neq c$, then it cannot be true both that $a = c$ and $a = b$.)

It is not clear what we should infer from this. One possibility is that the connectedness/continuity account is wrong. Another is that we should allow identity to admit degrees, and rewrite its logic. But one might conclude that these constant difficulties in finding links that guarantee both synchronic and diachronic identity of the mind may show merely that the theory’s implication that the unity of mind is an illusion needs to be taken seriously.

From this perspective, better arguments for a bundle theory may lie less in a priori considerations than in empirical

work by psychologists and brain scientists, which reveals striking breakdowns in mental unity (see Split brains). This suggests to some that the mind may best be viewed in terms not of linked experiences, but of hierarchies, systems and modules of monitoring and control of experience and activity, with all the unity there is being provided contingently by its embodiment in a normally functioning single organism. The bundle theory's natural home may thus turn out to be with functionalist accounts of mind.

Mind, child's theory of

Knowledge of other minds poses a variety of unusual problems due to the peculiarly private nature of mental states. Some current views, impressed by the contrast between the apparently direct access we have to our own mental states and the inaccessibility of others' mental states, argue that we understand the mental states of others by imagining that they are our own by 'simulation'. Other current views propose that we infer both our own mental states and the mental states of others by employing a set of conjectures arrived at through general inductive reasoning over experience: a 'folk psychology' or 'theory of mind'.

Experimental studies, by contrast, suggest that we possess an 'instinct' for comprehending the informational mental states of other minds. Children develop mental state concepts uniformly and rapidly in the preschool period when general reasoning powers are limited. For example, children can reason effectively about other people's beliefs before they can reliably calculate that 2 plus 2 equals 4. In the empirical study of the 'theory of mind' instinct there have been three major discoveries so far: first, that normally developing 2-year-olds are able to recognize the informational state of pretending; second, that normally developing children can, by the age of 4 years, solve a variety of false belief problems; and lastly, that this instinct is specifically impaired in children with the neurodevelopmental disorder known as 'autism'.

1 False belief understanding

The study of false belief has come to dominate much of the investigation of the child's theory of mind. Interest in false belief arose initially out of an article published by Premack and Woodruff (1978) on whether or not chimpanzees have a 'theory of mind'. The findings strongly suggested that chimpanzees have some awareness of an agent's goal because they made inferences concerning the use of objects as tools. In so far as understanding the use of tools in relation to an agent's goals is part of 'theory of mind', chimpanzees demonstrated a version of theory of mind. In a commentary on Premack and Woodruff's paper, Dennett (1978) has suggested that a stronger test of an animal's understanding of mental states would involve an understanding of false belief. In understanding false belief, the animal has to understand a belief that is not its own and therefore that does not simply reflect reality as the animal construes it. Such tests with chimpanzees have returned essentially negative results (see Premack 1988; Animal language and thought). However, the idea was taken up by Wimmer and Perner who developed scenarios for testing not chimpanzees, but human children.

In the first of these, Wimmer and Perner (1983) showed that 6-year-old children could predict an agent's behaviour from a false belief attributed by the children to the agent. Wimmer and Perner's original task was somewhat more complex than necessary. When Baron-Cohen, Leslie and Frith (1985) simplified the task, they found that the vast majority of normally developing 4-year-old children could successfully calculate Sally's belief in the following scenario. Sally puts her candy in a cupboard and goes out to play. Anne comes in, finds the candy and moves it to a nearby drawer. Now Sally comes back for her candy. Where does Sally think her candy is? Where will she look for it? Eighty-five per cent of 4-year-olds were able to attribute a false belief to Sally and thus to predict her erroneous behaviour. Children younger than 4, however, tend to predict Sally's behaviour from the candy's current position, as if Sally would know this.

Likewise, 4- but not 3-year-olds succeed in the following scenario from Perner, Leekam and Wimmer (1987). The child is shown a *Smarties* box and asked what it contains. '*Smarties*' [candy] is the invariable reply. The child is then shown that, actually, the box contains only a pencil. Disappointment. The pencil is placed back in the box and the lid closed again. The child is reminded that a friend is outside waiting to come in. Then the test question is asked, 'What will your friend say (/think) is in the box when we first show it to him/her? Again most 4-year-olds correctly predict '*Smarties*', while most 3-year-olds expect the friend to say, 'A pencil'.

The second key finding is that children suffering from the neurodevelopmental disorder known as 'childhood autism' have a focused and specific impairment in the capacity to recognize and reason about mental states. Autism is a life-long disorder resulting from complex biological causes (Frith 1989), characterized by social and communicative impairments beyond that expected on the basis of whatever degree of mental retardation may also be present (Wing and Gould 1979).

Baron-Cohen, Leslie and Frith (1985) presented three groups of children with the Sally/Anne scenario outlined above. One group consisted of normal 4-year-olds, one of Down's syndrome children and one of (older) autistic children. It was deliberately arranged that the autistic group had a mental age considerably higher than that of the Down's group. Furthermore, their IQs were in the borderline to normal range (mean 82), while the Down's children averaged an IQ of 64, in the moderately retarded range. The results of this study showed that, while around 85 per cent of both the normal and Down's groups correctly predicted Sally's false belief, only 20 per cent of the autistic group did so, despite their intellectual and age advantage. Any difficulty the autistic children might have with this task, therefore, cannot be attributed to general intellectual level.

In a follow-up study, Baron-Cohen, Leslie and Frith (1986) compared, across these same three groups, the children's ability to understand different types of events. They used a 'picture sequencing' task. Some picture sequences depicted physical-causal events, and some sequences depicted events which could only be appreciated if one took into account the (false) beliefs of the protagonists. The pictures in each sequence were jumbled and the children were asked to order each sequence so that the story 'made sense'. The results were again quite striking. The autistic children showed a specific difficulty. They performed well on the physical-causal stories but slumped to chance performance on the false belief stories. The younger normal children scored almost 100 per cent on these last stories, while the more retarded Down's group still out-performed the autistic group. Finally, analysis of the children's verbal descriptions of the stories showed that the autistic children produced much more physical-causal language but much less mental state language than the other two groups. Leslie and Frith (1989) subsequently showed that high-ability autistic children had difficulty understanding true-but-incomplete beliefs as well as false beliefs. Perner *et al.* (1989) showed that autistic children failed the *Smarties* task.

The findings of the above initial sets of studies on both normal and autistic children have subsequently been confirmed and extended in a large number of studies (see, for example, Baron-Cohen, Tager-Flusberg and Cohen 1993). Together, they raise the following question. How can the young brain attend to mental states when they cannot be seen, nor heard, nor felt? Leslie (1994) argues that this is the fundamental question to ask, because the child has to be able to attend to mental states before they can learn anything about them. The only plausible answer so far has been to suggest that children are equipped with a specialized cognitive mechanism that appears early in development when encyclopedic knowledge and general reasoning abilities are still severely limited. The pattern of development seen in childhood autism can then be understood as reflecting, at least in part, early biological damage to this specialized mechanism, damage which spares general intelligence (see Modularity of mind).

2 The significance of pretending

There is a certain form of false belief which is understood much earlier even than 4 years. This is 'make-believe' or pretending. Two-year-olds have no trouble recognizing when someone playfully pretends; when someone acts as if they believed an imaginary situation were real. Two-year-olds can readily figure out the specific content of the pretence (Leslie 1994). Likely as not, the 2-year-old will join in the game and proceed to contribute their own appropriate counterfactual inferences. This ability, which first emerges between 18 and 24 months, has been analysed by means of a cognitive model, the so-called 'metarepresentational theory of pretence', which identifies the main properties of the internal representations required by this ability (see Leslie 1987; Aesthetic attitude). These representations turn out to express the key information required to represent propositional attitudes. This led to the suggestion that these representational mechanisms form the specific innate basis of the child's capacity to acquire and elaborate a 'theory of mind'. Autistic children are impaired in their capacity to pretend and, for example, do not spontaneously pretend play. Indeed, this was a key consideration that led to the studies of belief understanding in autism outlined above.

One key feature of the capacity for pretence is that as soon as a child becomes capable of pretending in isolation, by themselves, they also become capable of understanding pretence-in-others (Leslie 1987; 1994). Thus, there is a 'developmental yoking' between being able oneself to pretend that a banana is a telephone and being able to understand that someone else is pretending that a banana is a telephone. This is strikingly different from the case of belief. Most psychologists agree that infants a few months olds can have beliefs, for example, that there is an object behind a screen. But no one thinks that these young infants simultaneously have the capacity to understand that someone else can have that same belief: there is no yoking between the capacity to have beliefs and the capacity to understand beliefs-in-others (see Belief; Propositional attitudes).

The metarepresentational theory of pretence referred to earlier explains the above pattern in the following way. Let us say, for expository purposes, that to have a belief is to stand in a certain kind of functional or processing relation to an internal representation (see Language of thought). Let us call this functional relation the 'belief box'. If a given representation *r* is placed in the belief box, then the organism comes to believe that *r*. In a similar vein, we might talk of a 'desire box', such that if *r* is placed in the desire box, then the organism comes to desire that *r*. In this vein, the metarepresentational theory of pretence says that there is no such thing as a 'pretend box'. Instead, in pretending, a representation 'I pretend that *r*' or a representation 'Mother pretends that *r*' is placed in the belief box and results, respectively, in solitary pretence or in understanding pretence-in-others. What determines the developmental emergence of pretending, then, is not the appearance of a 'pretend box', a new functional relation, but the appearance of new representations of the form '*X* pretends that *r*', that is, the appearance of metarepresentations. The understanding of belief-in-others likewise depends upon the emergence of metarepresentations of the form '*X* believes that *r*' and is delayed relative to the appearance of the 'belief box' at least as long as pretending is.

3 Why do normal 3-year-olds and autistic children fail false belief tasks?

How long after understanding pretence-in-others do children understand belief-in-others? So far what we have said suggests something of the order of two years. However, this may be an over-estimate. The 'standard' tasks used to assess false belief understanding seem to impose general problem-solving demands that 3-year-old children find hard to meet. These performance demands may be masking their underlying competence. Psychologists have been developing versions of the false belief tasks that make reduced demands and 3-year-olds do better on these simplified tasks.

For example, Wellman (1990) found that 3-year-olds could pass a version of the Sally/Anne task in which the position of the target object was not known but simply guessed. Wherever the child guessed, the experimenter said that Sally thought it was some other place. When asked to predict Sally's search behaviour, then, the child has to predict on the basis of Sally's different belief. Under these circumstances most 3-year-olds succeed. Apparently, the child's efforts to represent Sally's belief are not swamped by current reality if reality is only guessed at and not known for sure (see also Zaitchik 1991). In the *Smarties* task, certain memory cues built into the procedure seem to facilitate false belief success in 3-year-olds (Mitchell and Lacohe 1991). Roth and Leslie (1991) showed that normal 3-year-old children, while failing standard false belief tasks, may nevertheless attribute propositional attitudes to participants in a conversation. Roth and Leslie's autistic subjects, however, failed to perform even at the 3-year-olds' level.

If 3-year-olds fail standard false belief tests because of performance limitations, might not the same be true for autistic children? It is nigh impossible to think up, let alone rule out, every potential general processing resource that might be required by these tasks and be impaired in autism. Many such accounts are possible: working memory, language ability, visual imagery ability, abstract reasoning, executive functioning, a cooperative attitude, and so on. Fortunately, such explanations can be ruled out by the following results. Zaitchik (1990) devised a task that closely parallels the standard false belief tasks but instead of an agent forming a belief that subsequently goes out of date, the task involves a camera taking a Polaroid photograph that subsequently goes out of date. So the camera takes a photograph of the candy in the cupboard. The photograph is placed faced down on the table without the child seeing it (after all, the child does not get to see Sally's belief either). Now the candy is moved from the cupboard to the drawer. The usual 'control' questions are asked: 'Where was the candy when I took a photograph of it?' and 'Where is the candy now?'. As usual, the child must get these questions right if they are to be tested further. The child is asked, 'In the photograph, where is the candy?'.

Results with normal children show that, typically, 3-year-olds fail both the out-of-date photograph and belief tasks, while most 4-year-olds pass both. However, if a normal child passes only one of these tasks, there is a reliable tendency for them to pass the false belief rather than the out-of-date photograph task. Leslie and Thaiss (1992) showed that autistic children show near ceiling performance on out-of-date photographs while being severely impaired on the similar out-of-date belief task. (Incidentally, this effect is not restricted to cameras and photographs; it works just as well with maps and drawings.) This is impressive evidence for the domain specificity of autistic impairment. It also contradicts the perhaps natural assumption that understanding mental states and understanding representations should simply be different facets of the same psychological mechanism (see, for

example, Fodor 1992).

4 Alternative theories of 'theory of mind' development

Other current positions in the literature view the development of 'theory of mind' knowledge as the discovery by young children of a succession of 'theories' much as scientists have created and abandoned successive theories of the natural world (for example, Gopnik 1993; Perner 1991; Wellman 1990; see Folk psychology). However, the obvious differences between the historical achievements of talented individuals and the rapid, early and uniform acquisitions of ordinary preschool children imply in the latter case a process more akin to the unfolding of an albeit 'articulated' instinct than to the scientific process. Yet another recent position wants to deny the existence of theory-like knowledge or inference over data structures by substituting the notion that we 'simulate' the mental states of others (Harris 1992; Goldman 1992). Simulation theory proposes that we understand other people's actions by modelling their circumstances and predicting their actions by means of the very mechanisms that generate our own actions. We are said to run our action-planning system 'off-line', supplying it with 'pretend' inputs, to 'simulate' the other person's mental life by, as it were, placing our self 'in the other person's shoes'.

However, there are a number of quite different processes that could be called 'simulation' and their contributions to 'theory of mind' abilities will each have to be determined empirically (see Nichols *et al.* 1996). It may well turn out that 'simulation' is one of the abilities associated with deploying folk psychological knowledge. However, Leslie and German (1995) have pointed out a number of problems for the radical claim that the existence of simulation abilities means there is no need for 'theory of mind' (meta) representations.

Neither of these current alternative views has addressed the fundamental problem of 'theory of mind' development, namely, how is it possible for the young brain to attend to mental states in the first place? The metarepresentational theory was designed for this problem. The theory proposes that the young brain attends to an agent's behaviour and infers an underlying causal state of the agent having the properties specified by the metarepresentation. The metarepresentation is computed by a specialized, probably modular, innate mechanism. This mechanism allows the young brain to attend to and learn about invisible mental states and promotes the early and rapid development of 'theory of mind'. When early occurring biological damage prevents the normal expression of this mechanism in the developing brain, the result is the core symptoms of autism.

Mind, computational theories of

The computational theory of mind (CTM) is the theory that the mind can be understood as a computer or, roughly, as the 'software program' of the brain. It is the most influential form of 'functionalism', according to which what distinguishes a mind is not what it is made of, nor a person's behavioural dispositions, but the way in which the brain is organized. CTM underlies some of the most important research in current cognitive science, for example, theories of artificial intelligence, perception, decision making and linguistics.

CTM involves a number of important ideas. (1) Computations can be defined over syntactically specifiable symbols (that is, symbols specified by rules governing their combination) possessing semantic properties (or 'meaning'). For example, addition can be captured by rules defined over decimal numerals (symbols) that name *the numbers. (2) Computations can be analysed into 'algorithms', or simple step-by-step procedures, each of which could be carried out by a machine. (3) Computation can be generalized to include not only arithmetic, but deductive logic and other forms of reasoning, including induction, abduction and decision making. (4) Computations capture relatively autonomous levels of ordinary psychological explanation different from neurophysiology and descriptions of behaviour.*

1 Syntax, semantics and algorithms

Crucial to understanding computational theories of mind (CTM) is the distinction between the syntax and the semantics of a symbol system. *How* symbols may be combined comprises the syntax of a system and what the symbols *mean* or *name* comprises its semantics. For example, consider three different notational systems for numbers: decimal numerals ('1', '2', '3',…), Roman numerals ('I', 'II', 'III',…) and binary numerals ('1', '10', '11',…). These different types of *numerals* name the same *numbers* ('5' names the same number as 'V' and '101') but the rules for combining the numerals in calculations are very different. In other words, these systems each have a different syntax, but (approximately) the same semantics.

When children learn arithmetic, they learn reliable rules, or 'algorithms', for computing *syntactically* with numerals (symbols) in ways that mirror their *semantics* (in particular, the arithmetical relations among the corresponding numbers). Children doing calculations with decimal numerals should get the same answers as a computer working in binary, but the algorithms each uses look very different.

An algorithm is a 'mechanical' step-by-step procedure operating on syntactically well-defined symbols in a way that captures relations among the things the symbols represent. Alan Turing developed a general account of algorithms, conceiving what are called 'Turing machines', perfectly mechanical computing devices that arrive at a determinate answer or 'output' to a question, given certain data or 'input' (see Turing machines). According to the influential 'Church-Turing thesis' Turing machines can systematically compute anything that is intuitively 'computable' (see Church's thesis). This idea is the inspiration for much of the modern computer industry. CTM extends it to psychology: the suggestion is that all intelligent processes can be systematically decomposed into algorithms consisting of steps that can be executed by primitive processors of a machine.

2 Primitive processors

The specific architecture of a Turing machine involves a 'tape' consisting of an infinite number of individual cells and a 'scanner', whose primitive processes consist in registering whether it is scanning a '1' or a '0', and then moving left and right from cell to cell (see Turing machines). This is only one among many possible computational architectures. What is essential to a computer is merely that the primitive processes be realizable by some physical means or other. To make computational theories of mind (CTM) remotely plausible as an account of the *human* mind, we will think here in terms of the kinds of electrical devices that seem at least to be available in the human nervous system (but are also exploited in commercial computers).

A good example of a primitive processor is a 'gate'. An 'and'-gate is a device that accepts two inputs and emits a single output. If both inputs are '1's (that is, sum to 2), the output is a '1'; otherwise, the output is a '0'. An 'exclusive-or' (either but not both) gate is a 'difference detector': it emits a '0' if its inputs are the same and it emits a '1' if its inputs are different (or sum exactly to 1).

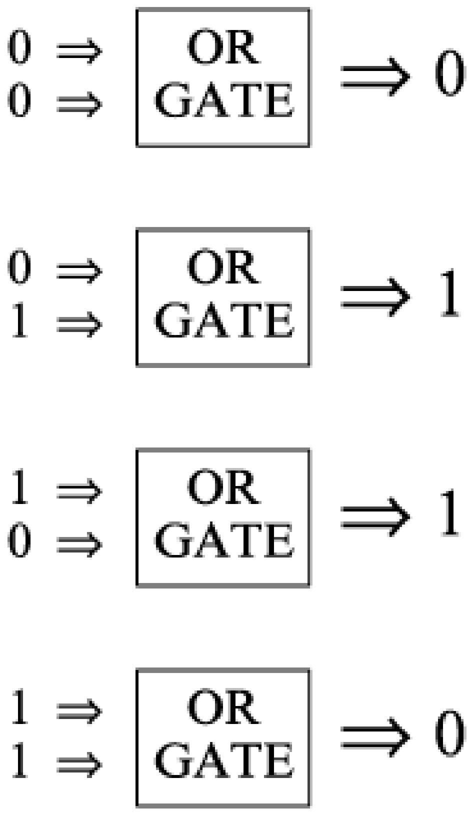

Figure 1a. Firing pattern of an “exclusive-or”-gate

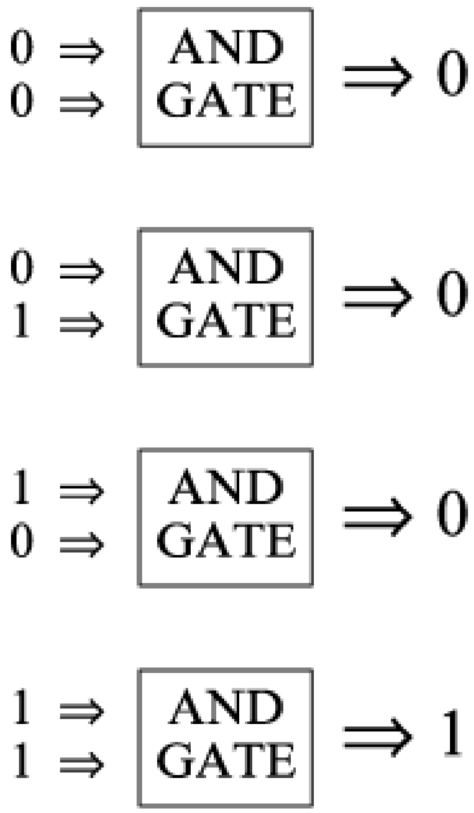

Figure 1b. Firing pattern of an “and”-gate

This talk of ‘1’ and ‘0’ is a way of thinking about the ‘bi-stable’ states of computer representers: they are almost always in one or the other of two states; the in-between states are not exploited computationally.

Using these gates, one could construct a binary ‘adder’ that operated according to the following rules of binary addition:

$0 + 0 = 0$

$1 + 0 = 1$

$0 + 1 = 1$

$1 + 1 = 10$

The two digits to be added are connected both to an ‘and’-gate and to an ‘exclusive-or’-gate as illustrated.

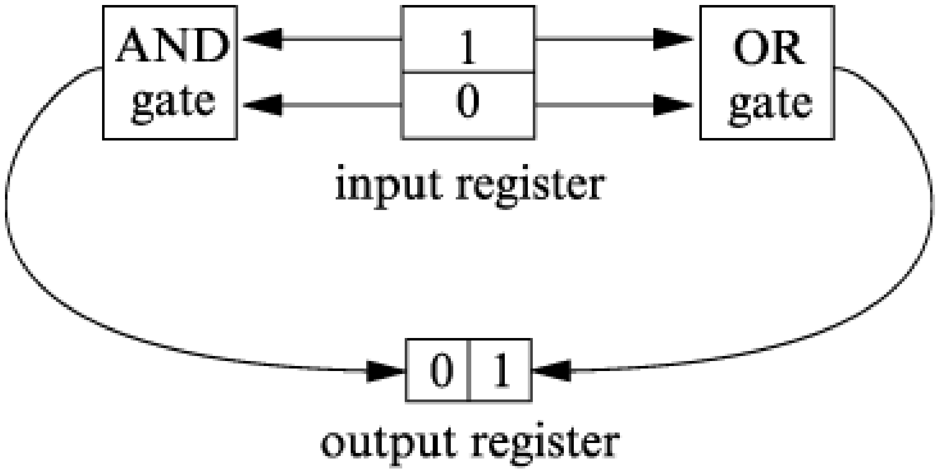

Figure 2a. Adder computing 1 + 0 = 1

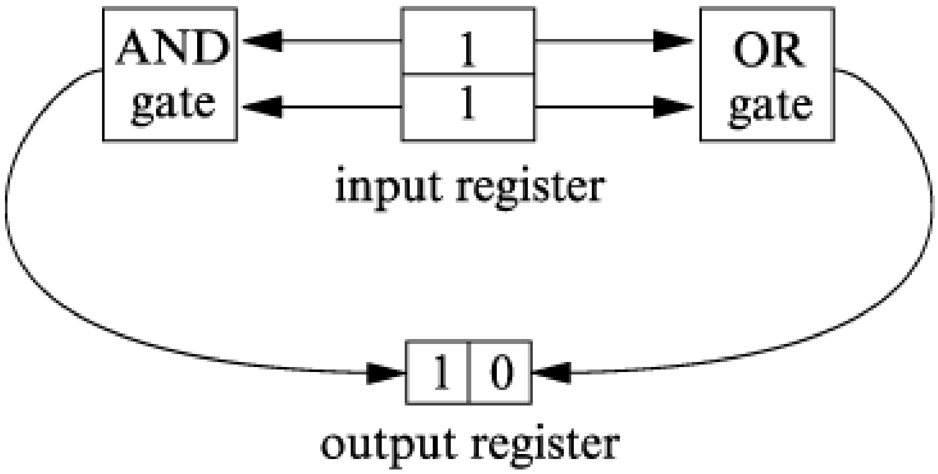

Figure 2b. Adder computing 1 + 1 = 10

Consider figure 2a first. The digits to be added are ‘1’ and ‘0’, and they are placed in the input register (the top pair of boxes). The ‘exclusive-or’-gate sees different things, and so outputs a ‘1’ to the right-most box of the answer register (the bottom pair of boxes). The ‘and’-gate outputs a ‘0’ except when it sees two ‘1’s, so it now outputs a ‘0’. In this way, the circuit computes ‘ $1 + 0 = 1$’. For this problem, as for ‘ $0 + 1 = 1$’ and ‘ $0 + 0 = 0$’, the ‘exclusive-or’-gate does all the real work. The role of the ‘and’-gate in this circuit is ‘carrying’, which is illustrated in figure 2b. The digits to be added, ‘1’ and ‘1’, are again placed in the top register. Now, both inputs to the ‘and’-gate are ‘1’s, so the ‘and’-gate outputs a ‘1’ to the left-most box of the answer (bottom) register. The ‘exclusive-or’-gate puts a ‘0’ in the right-most box, and so we have the correct answer, ‘10’.

3 Syntactic engines

The key idea behind the adder is that of a mirroring, or an isomorphism, between syntactic relations among numerals and their semantics, namely the relations among the numbers the numerals represent (see §1 above). This idea need not be confined to arithmetic. In their development of modern ‘formal’ logic, Frege and Russell showed how deductive logic can be formalized: that is to say, it can be characterized in terms of syntax, and this syntax

can be characterized in terms of the physical *form* of sentences that receive a systematic semantic interpretation. In particular, it can be shown that a certain set of syntactically and formally specifiable rules is adequate to capture a significant class of deductively valid arguments (see Formal languages and systems).

Ordinarily, sentences in logic are manipulated by people consciously following explicit rules, such as *modus ponens*, that are defined over their syntactic form, and it is often feared that CTM is committed to 'homunculi' in the brain executing the rules. However, the rules could also be obeyed by a Turing machine or, alternatively, a machine constructed along the lines of our simple adder: for example, whenever the machine detected sentences of the form 'P' and '$P \Rightarrow Q$' as input, it could print 'Q' as output, thereby obeying *modus ponens*. In general, Turing showed that there could be a sequence of physical processes that realized any finite piece of deductive reasoning simply as a consequence of its physical organization. Consequently, one's reasoning could be in accordance with the rules of logic, not by virtue of someone representing and following them, but as a result of the causal organization of the brain. This is what is meant by the expression a 'syntactic engine driving a semantic one' (see Fodor 1975, 1980; Newall 1980). As Dennett (1975) put it, intelligent processes are broken down into separate processes so stupid that a mere machine could execute them.

Note that, although the machine's operations can be defined without mentioning the meaning of symbols, this does not entail that the symbols are meaningless, any more than the fact that bachelors are defined without reference to hair entails that bachelors are bald. Indeed, computations are standardly defined over symbols that are presumed to have some meaning or other (a point often missed by critics of CTM such as Searle (1984: 33); see Chinese room argument).

How do symbols in computers acquire meaning? In the case of most artificial computers, their semantics are pretty much whatever their designers say they are. However, this might not always be so: philosophers have proposed a wide variety of conditions, involving both the internal states of a system, and their (for example, causal and co-variant) relations to external phenomena, that arguably would provide natural conditions for the states of a machine - or of an evolved animal like ourselves - having specific meanings (see Semantics, informational; Semantics, teleological; Semantics, conceptual role). These theories could provide semantic interpretations for the syntactic states postulated by CTM.

4 Other forms of reason

Deductive arguments were the inspiration, and remain the clearest success, for CTM. Similar hopes are entertained by many philosophers and cognitive scientists for a logic of induction, abduction, practical reason and decision making (see Inductive inference; Inference to the best explanation; Rationality, practical). The following affords an extremely simple example of what they have in mind.

Imagine that a computer is provided with programs that perform operations on sentences in a formal language like that of modern symbolic logic, and that it is supplied with certain hypotheses, say, about circles and squares, to which it assigns certain initial probabilities. A video camera presents it with some inputs that directly cause it to access those hypotheses, deducing from each of them, one by one, the consequences regarding the character of the input that would be expected if the hypothesis were true. These consequences are compared in each case with the actual input that is received, and that hypothesis is 'accepted' which satisfies some threshold value of a function of the initial probabilities and the highest degree of fit between its consequences and that input.

Imagine also that the machine is capable of performing certain basic actions: for example, whenever certain sentences (for example, 'Move right!') are in certain 'command' registers, then its 'arms' (say) are caused to move in a corresponding way. And suppose that the sentences that end up in these command addresses are the result of a program that spells out familiar decision-theoretic reasoning ('If more squares are wanted, and the probability of getting some by moving right is greater than by moving left, then move right') that are applied to an arbitrary set of basic preferences that are wired into the machine (say, that it prefers to replicate squares and obliterate circles).

If the machine now operated according to these programs, its actions would seem to be explainable along familiar mentalistic lines. Although reasoning in most animals is massively more complex than this, these programs would seem to capture what is essential to such processes as perception, hypothesis testing, belief, desire and decision making. That, at any rate, is the claim of CTM.

5 Gödel's incompleteness theorem

It is often thought that Gödel's famous 'incompleteness' theorem, which proved that no formal system can prove all the truths of arithmetic (see Gödel's theorems §§3-4), showed that the human mind cannot be a computer, and that CTM must therefore be false (see Lucas 1961; Penrose 1989). After all, Gödel appreciated the truth of the very sentences he is supposed to have proved to be unprovable!

There are a great many problems in this reasoning (for a start, CTM is not committed to all reasoning being deductive), but perhaps the most basic one arises from not appreciating the essentially disjunctive character of Gödel's theorem: what he proved was that *either* a formal system of arithmetic was inconsistent *or* it was incomplete. If people managed to do something that counted as proving the relevant undecidable sentence for their own system of arithmetic, they would do this at the expense of no longer being consistent: a contradiction could now be derived from their axioms. But this would not be a particularly remarkable fact: they would not explode or die. They would simply be disposed to believe a contradiction (a disposition many of us possess already). It is true that there are things no machine can do, namely, prove all the truths of arithmetic without contradicting itself; but it has yet to be established that any human being can do them either (see Putnam 1960; Lewis 1969, 1979).

6 Different modes of computation

There are many different ways in which computations can be carried out. Along lines closest to the original computers described here, there are the 'classical', 'symbolic' approaches that typically involve a 'language of thought' that is encoded and manipulated in the hardware of the computer (see Fodor 1975; Newall 1980; Language of thought). But more recently there have emerged 'non-symbolic', 'connectionist' approaches that eschew sentence-like structures, and exploit networks of interconnected cells subject to varying degrees of excitation (see, for example, Churchland and Sejnowski 1992; Connectionism). However, the two approaches need not be exclusive: through ingenious encoding, connectionist programs can be (and standardly are) run on computers constructed along classical lines, and vice versa. This is why one cannot tell simply by looking at the physical architecture of the brain whether the mind 'really' has a classical or connectionist '*cognitive* architecture'.

7 Different explanatory levels

This last point highlights an issue central to computational approaches to the mind: that there may be many different explanatory levels for describing the brain (see Explanation). Note, for example, that what is essential to the success of the computations of even our little adder (see §§2-3 above) does not depend upon the gates being realized electronically. An indefinite variety of devices (composed of pipes of water, or of mice in traps) could obey the same rules. Two primitive processors (such as gates) count as computationally equivalent if they have the same input-output function, that is, the same actual and potential behaviour, even if one works hydraulically and the other electrically. So CTM describes the organization of the brain at a level that abstracts from most of its biology.

This is not to say that the computer model is incompatible with a biological approach. Sometimes important information about how a computer works could be gained by examining its circuits. As Lycan (1981) emphasizes, there may well be indefinitely many different levels of description and explanation of a system's processes, within both CTM and biology itself.

CTM is thus a paradigm of a functionalist approach to the mind, whereby mental states are individuated by their role in an organization (see Functionalism). Unlike dualism and physicalistic reductionism, it is not committed to any particular claims about the substance out of which minds might be composed. But, unlike behaviourism, CTM is not entirely indifferent to what goes on inside the head.

In particular, although computational equivalence of primitive processors is defined in terms of their input and output, the equivalence of *non*-primitive devices is not. Consider two multipliers that work via different programs. Both accept inputs and emit outputs only in decimal notation. One of them converts inputs to binary, does the computation in binary, and then converts back to decimal. The other does the computation directly in decimal. These are not computationally equivalent multipliers despite their identical input-output functions. Thus, not only might creatures made of different stuff have the same mental lives, but behaviourally indistinguishable creatures

might have very different ones.

Mind, identity theory of

We know that the brain is intimately connected with mental activity. Indeed, doctors now define death in terms of the cessation of the relevant brain activity. The identity theory of mind holds that the intimate connection is identity: the mind is the brain, or, more precisely, mental states are states of the brain. The theory goes directly against a long tradition according to which mental and material belong to quite distinct ontological categories - the mental being essentially conscious, the material essentially unconscious. This tradition has been bedevilled by the problem of how essentially immaterial states could be caused by the material world, as would happen when we see a tree, and how they could cause material states, as would happen when we decide to make an omelette.

A great merit of the identity theory is that it avoids this problem: interaction between mental and material becomes simply interaction between one subset of material states, namely certain states of a sophisticated central nervous system, and other material states. The theory also brings the mind within the scope of modern science. More and more phenomena are turning out to be explicable in the physical terms of modern science: phenomena once explained in terms of spells, possession by devils, Thor's *thunderbolts, and so on, are now explained in more mundane, physical terms. If the identity theory is right, the same goes for the mind. Neuroscience will in time reveal the secrets of the mind in the same general way that the theory of electricity reveals the secrets of lightning. This possibility has received enormous support from advances in computing. We now have at least the glimmerings of an idea of how a purely material or physical system could do some of the things minds can do.*

Nevertheless, there are many questions to be asked of the identity theory. How could states that seem *so different turn out to be one and the same? Would neurophysiologists actually see my thoughts and feelings if they looked at my brain? When we report on our mental states what are we reporting on - our brains?*

1 Origin of the identity theory

The identity theory of mind holds that each and every mental state is identical with some state in the brain. My desire for coffee, my feeling happy, and my believing that the dog is about to bite are all states of my brain. The view is not that mental states and brain states are correlated but that they are literally one and the same. Despite its name, the identity theory of mind is strictly speaking not a view about the mind as such, but about mental phenomena. However, most protagonists of the identity theory, and most contemporary philosophers of mind if it comes to that, hold some version of the view that the mind is a construction out of its states in somewhat the way that an army is a construction out of its soldiers.

The identity theory of mind arose out of dissatisfaction with dualism, and with behaviourism as an attempt to avoid dualism. According to dualism, mental states are quite distinct from any material states, including brain states (see Dualism). The most famous challenge to dualism is to give a satisfactory account of the causal interactions between mental states and material states, and most especially to give a satisfactory account of causation from mental states to bodily occurrences. We believe that sometimes my desire for ice cream causes my arm to move in such a way that an ice cream is in my mouth, that my pangs of hunger cause me to tighten my belt, and so on. But how do states allegedly 'outside' the material world cause material goings on like arm movements? How do they do this in such a way as to avoid violating the various conservation laws in physics? And how do they do this in such a way as not to conflict with what the physical sciences, and especially neuroscience, tell us about how bodily movements are caused?

The last question is particularly pressing. The success of the physical sciences in explaining phenomena in their own, physical, terms has been striking. We now know that lightning is not caused by Thor's actions, that epilepsy is not caused by demonic possession, and that plants do not grow because they contain a vital essence but because their cells divide (see Vitalism). It is hard to believe that bodily behaviour is unique in resisting in-principle explanation in purely physical terms. The dualist can respond to this challenge by denying the common-sense view that mental states sometimes cause bodily behaviour, a position known as epiphenomenalism. This position holds that although physical states on occasion cause mental states, mental states themselves never cause anything, being mere epiphenomena of the brain states that, along with the appropriate material surroundings, are the true causes of the behaviour we associate with mental states. Apart from flying in the face of common-sense, this position makes it hard to see why the mind evolved (see Epiphenomenalism).

Behaviourism treats mental states in terms of behaviour and dispositions to behaviour. Its inspiration comes from facts such as these: that those creatures we credit with mental states are precisely those manifesting sophisticated behaviour and possessing sophisticated behavioural capacities; that psychology became a serious science when psychologists started to investigate the mind via the investigation of behavioural capacities; and that there are conceptual links between mental states and behaviour - it is, for instance, part of the concept of an intention that having an intention goes along with behaving in a way that tends to fulfil it, and it is part of the concept of intelligence that the intelligent are better problem solvers than the unintelligent (see Behaviourism, analytic).

Behaviourists delight in pointing out that it is hard to see how dualists could explain the last two points. Why should investigation of an immaterial realm be especially aided by looking at behaviour? How could the way things are in some immaterial realm be *conceptually* linked to brute behavioural facts? However, for our purposes here the crucial point is that behaviourists, like dualists, have trouble over the causation of behaviour.

The common-sense position is that mental states are causally responsible for behaviour - the itch causes the scratching - and responsible for behavioural dispositions and capacities - people's intelligence is responsible for their capacity to solve hard problems. But then mental states are not the same as behaviour and behavioural dispositions and capacities, being rather their underlying causes. And so they are, says the identity theorist. Mental states are those brain states that all the scientific evidence points to as being causally responsible for the behaviour, and behavioural dispositions and capacities, distinctive of those creatures we credit with a mental life.

2 Early objections

Here are some of the many objections that greeted the identity theory when it became well known through, especially, Smart (1959).

It was objected that the ancients knew about mental states while knowing next to nothing about the brain. How could this be if mental states are identical with brain states? However, as identity theorists observed, science has established many identities that were unknown to the ancients. They did not know that lightning is identical with an electrical discharge, temperature in gases is mean molecular kinetic energy, and water is H_2O. The identity of mental states with brain states is, identity theorists urged, of a piece with scientific identities in general. We learned, for example, that temperature is mean molecular kinetic energy by discovering that it is mean molecular kinetic energy that is responsible for the phenomena we associate with temperature. In the same general way, identity theorists claim, we have discovered that mental states are brain states by discovering that brain states are responsible for the behavioural phenomena that we associate with mental states, and we will discover which particular brain states are which particular mental states by discovering which particular brain states are responsible for the behavioural phenomena associated with those mental states.

Identity theorists also noted that water, lightning, and temperature do not present themselves to us *as* H_2O, electrical discharge, and mean molecular kinetic energy, respectively; so it cannot be an objection to their theory that mental states do not present themselves *as* brain states.

Many objected that the identity theory violates Leibniz's Law that if x = y, then x and y share all properties (see Identity), on the ground that mental states and brain states differ in their properties. An after-image is, say, yellow and in front of my face, but my brain states are not yellow, and are inside my head; again, an itch is, say, in the middle of my back, but my brain is not in the middle of my back. They also pointed out that brain states are at a certain temperature but that it is surely absurd to hold that my belief that the Earth is not flat is at a certain temperature.

Identity theorists replied by arguing that our talk about mental states is, from a logical point of view, misleading. We talk as if mental states involved relations to mental objects. We say, for example, 'I have a headache', and this apparently has the same logical structure as 'I have a car': in both cases we seem to be asserting a relation between a person, me, and an object - a headache in one case, a car in the other. However, as identity theorists noted, cars are very different from headaches: cars can exist without their owners (if I die suddenly, my car will go on existing), but headaches cannot exist independently of being experienced (if I die, any headache of mine necessarily dies with me). Headaches, and mental states in general, are necessarily someone's. In consequence, they argued, we should think of headaches in the way we think of limps: limps are not things we have when we

limp. When I say that I have a limp, I am simply saying that I limp; similarly, to say that I have a headache is to say that my head aches. Attributing properties to aches and limps is really attributing properties to ach*ings* and limp*ings*. To have a bad limp is to limp badly, and to have a winning smile is to smile winningly; likewise, to have a bad headache is to have a head that aches badly (see Mental states, adverbial theory of). Strictly speaking, there are no mental objects, and so, in particular, no after-images to be yellow and in front of faces, and no itches to be in backs; there are experiences of having after-images and of having one's back itching. These experiences are not yellow, not in front of us or in our backs, and so the fact that brain states are not yellow, not in front of us and not in our backs is no objection to the identity theorist's claim that these experiences are identical with brain states.

The discussion of belief followed a different course. There is an important distinction between my believing something, my state of belief, and what I believe. My believing that there is a tiger before me is, most likely, caused by seeing a tiger and is a state of mine, whereas what I believe - that there is a tiger before me, the *proposition* believed, as it is often put (see Propositional attitudes) - is not caused by my seeing the tiger and is not a state of mine. Again, there is my belief that the Earth is not flat, thought of as a state of mine that causes me, say, to reassure a traveller that they do not have to worry about falling off the edge, and there is the proposition that the Earth is not flat, which is *what* I accept. Now, the identity theory is not a view about the objects of belief, the propositions; it restricts itself to claiming that the state of believing is a state of the brain. And, identity theorists argued, although it would be absurd to hold that the objects of belief are at a certain temperature, it is not absurd to hold that the believings are.

Finally, some philosophers objected that the behaviour associated with having a mind, and in particular, that associated with intelligence, rationality and free action, displays a flexibility and sophistication incompatible with a purely material etiology. There are complex issues here, but we can note two serious problems for this objection. First, computers have enlarged our conception of the behavioural flexibility and sophistication compatible with a purely material etiology; and, second, it is hard to see how having an *immaterial* etiology would make any difference to the conceptual issues at stake (and, of course, quantum mechanics has broken the tie between having a material etiology and being determined).

3 Qualia

There was, however, one early objection to the identity theory that proved harder to dismiss. It concerns a perennial problem in the philosophy of mind: the nature of conscious experience and the sensuous side of psychology. But first, some stage setting.

The identity theory of mind is typically seen as part of the programme of giving a purely naturalistic or physicalistic view of the mind (see Materialism in the philosophy of mind). It is not a species of dual attribute theory of mind, according to which, although mental states are brain states they are brain states with special, non-physical properties, properties quite distinct from the kinds of properties neuro-science in particular, and the physical sciences in general, might attribute to them. The problem with dual attribute theories is that the question of how, in the light of what science is teaching us about the physical nature of the causation of behaviour, these non-physical properties could be causally relevant to behaviour seems just as pressing as the question, raised earlier, of how non-physical states could be causally relevant to behaviour. In consequence, most identity theorists see their theory as a purely naturalistic account of the mind: the denial of 'spooky' properties or attributes is as much part of the theory as the denial of 'spooky' entities or states.

The perennial objection is that the identity theory, when seen, as it should be, as part of a purely naturalistic view of the mind, leaves out the nature of conscious mental experience, the phenomenal side of psychology. We distinguish those mental states that are not associated with a characteristic 'feel' from those that are. Paradigmatic examples are belief, on the non-sensuous side, and bodily sensations and sensory perceptions, on the sensuous side. My belief that the world is round does not have a characteristic conscious feel available to introspective awareness; my itch and my sensing of a red sunset do. But, runs the objection, no amount of neurophysiological information about our brains tells us what it is like to itch, see a sunset, or smell a rose. Protagonists of this objection often use the term 'qualia' ('quale' is the singular) for the special properties that they insist that the identity theory leaves out of account. Typically, they hold that these qualia are epiphenomenal features. They avoid the implausibility of denying that pains and sensings of red *per se* are causally inefficacious but acknowledge that they have to allow that the *distinctive feel* of pains and sensings of red is causally irrelevant (see

Qualia).

4 Functionalism and the identity theory

When identity theorists first discussed the qualia objection they urged that when we itch, smell a rose, and quite generally when we are in a mental state, we are not introspectively aware of the intrinsic nature of the mental state. For they granted, as we noted earlier, that mental states do not present themselves to us as states of the brain. The identity theorists held that what happens when we introspect is that we are aware of highly relational properties of our mental states, properties like being like what goes on in me when a pin is stuck in me (in the case of pain), being like what goes on in me when I see blood and geranium petals (in the case of sensing red), and being of a kind apt for the production of scratching behaviour (in the case of itches). In bringing relational properties into the picture, the early identity theorists can be seen as precursors of functionalist theories of mind. For functionalism is a theory according to which what makes something the mental state it is is a highly relational feature of it, that feature known as its functional role.

According to functionalism, we can think of mental states as causal intermediaries between inputs from the environment, outputs in the form of behavioural responses, and other mental states. Pain, for instance, is an internal state that is typically caused by bodily damage, and typically causes the desire that it itself cease along with behavioural responses that tend to minimize the damage. The perception that there is coffee in front of me is an internal state typically caused by coffee in front of me, which in turn causes belief that there is coffee in front of me, and this belief, when combined with desire for coffee, typically causes movement towards the coffee. Mental states are, that is, specified in terms of their place in a huge network of interlocking states (of which we have just described a tiny fragment) (see Functionalism). Our concern here is with the implications of this general approach for the identity theory.

Functionalism can be, and often is, regarded as entirely consonant with the identity theory, being indeed a good way of arguing for it; or functionalism can be, and often is, regarded as a major objection to the identity theory. It all depends on the kind of identity theory.

If mental states are defined by their place in a network, then the question of what some given mental state *is* comes down to the question of what state occupies the relevant place in the network. An analogy: money can be defined in terms of a characteristic functional role, a role we are all only too familiar with through our knowledge of what you can do if you have money, and cannot do if you do not have money. In consequence, the question of what money is is the question of what plays, or occupies, the money-functional role, be it paper notes, coins, cowrie shells, or whatever. But, identity theorists observe, by far the most plausible candidates for what play the functional roles associated with mental states are various states of the brain. Thus, functionalism gives us a simple argument for the identity theory of the following structure: pain = what plays the pain-role; what plays the pain-role = a state of the brain (say, C-fibres firing); therefore, pain = C-fibres firing. And likewise for all the mental states. Identity theorists who see the identity theory as a natural offshoot of functionalism, often refer to the identity theory as ‘central state materialism’.

Approaching the identity theory through functionalism commits identity theorists to an anti-essentialist theory of mind. For the brain state that occupies the pain-role and so is, according to them, pain, might not have done so, and so might not have been pain. And the same goes for all mental states. Early expositions of the identity theory made this point by insisting that the identity of pain with, say, C-fibres firing was a *contingent* identity, and drew an analogy in this regard with the scientific identities we mentioned before. However, at least some of these identities are arguably necessarily true. It is arguable that water is necessarily H_2O. Certainly, we had to discover the identity of water and H_2O by empirical investigation, which makes it an a posteriori matter, but what we discovered was an essential feature of water. However, the identity theory must hold that the identities it posits are contingent. They are like the identity of the President of the United States in 1997 with Bill Clinton, which is contingent because that which occupies the role definitive of being President in 1997 is a contingent matter. (Dole was swimming against an economic tide, not a logical one.)

Although functionalism is a good way of arguing for the identity theory, it is a major objection to one kind of identity theory. We noted that identity theorists appeal to scientific identities in explaining and introducing their theory. These identities concern kinds or *types*. When scientists tell us that lightning is an electrical discharge, they

are not merely telling us that the instance or *token* of lightning we saw last night is an instance or token of an electrical discharge; they are telling us, in addition, about what kind of happening lightning in general is. Again, the claim that temperature is mean molecular kinetic energy is a claim about kinds or types; it tells us what the property of temperature (in gases, anyway) is - namely, mean molecular kinetic energy. This suggests that we should think of the (mind-brain) identity theory as a type-type identity theory. Moreover, the theorists' favourite illustration - 'Pain = C-fibres firing' - is a type-type identity statement.

The problem is that different types of state might occupy the pain-role in different creatures. Perhaps it is C-fibres firing in humans but D-fibres firing in dolphins. But dolphins with their D-fibres firing would then be just as much in pain as we are when our C-fibres are firing. It is the role occupied, not the occupier, that matters for being in pain according to functionalism. And the point is independently plausible. We feel sorry for dolphins that exhibit all the signs of pain despite not knowing in any detail how intrinsically alike our and their brains are. But the identity theorist cannot allow both that pain = C-fibres firing, and that pain = D-fibres firing. That would, by the transitivity of identity, lead to the false contention that C-fibres firing = D-fibres firing.

Two responses are possible. Identity theorists can retreat to a token-token identity theory. Each and every token or instance of mental state M is some token brain state, but mental types are not brain types, being instead functional types. Alternatively, they can allow that the identities between mental types and brain types may need to be restricted. Think again of the example of money. Although different types of things are money in different societies, we can make true identity claims about the types of things that are money in the different societies. For instance, money in our society = notes and coins produced by the mint, whereas money in early Polynesian society = cowrie shells (or whatever). Similarly, although temperature in gases = mean molecular kinetic energy, in substances of which the molecules do not move freely it is something else. In the same way, if indeed it is C-fibres in us but D-fibres in dolphins that play the pain-role, then identity theorists must restrict themselves to 'Pain in humans = C-fibres firing' and 'Pain in dolphins = D-fibres firing'. The question of what humans in pain and dolphins in pain have in common would remain, of course, for they would not *ex hypothesi* share the same kind of brain state. And the identity theorists' answer must be that what they would have in common would be that each has a state inside them playing the pain-role, although not the same state.

Mind, Indian philosophy of

Despite the enormous complexity of the Indian philosophical tradition, all the different schools developed within a common worldview mapped out by the three ideas of saṃsāra, karma *and* mokṣa *(or* nirvāṇa *in the case of Buddhism). This soteriological context, which informs much of Indian philosophy, is of particular importance for the philosophy of mind, giving it a distinctive character unparalleled in the Western tradition. Speculations about the nature of mind originated in Upaniṣadic teachings that salvific knowledge comes from looking inwards. We see in the earlier Upaniṣads (from about the eighth to the fifth centuries* BC*) a careful classification of normal states of consciousness, but eventually liberation from the cycle of rebirth and suffering was framed in terms of the individual's ability to manipulate and ultimately transcend such states through the pursuit of a set of ascetic practices known as* yoga. *These ascetic practices led to a liberating state of consciousness which the Upaniṣads equated with the realization of a transcendental Self known as the* ātman. *With the development of Buddhist thought in India (from the fifth century* BC*), the philosophical tradition became divided. Generally, Buddhist schools of thought were united in their opposition to the existence of the* ātman, *whereas the so-called orthodox Hindu schools continued to favour the Upaniṣadic position. The practical quest for liberation from suffering remained central, however, to the entire philosophical tradition as the Upaniṣads gave way to a more systematic philosophizing. Subsequently, Buddhists and non-Buddhists alike continued to accept the results of meditative practice as being a legitimate concern for philosophical speculation. A dialectical relationship between theory and practice meant that philosophical disagreements created not just differences in the interpretation of meditative experiences, but also shaped such practices themselves in different ways. The apparent empirical vein of the Upaniṣads was also continued in all schools of thought, leading to richer and more detailed phenomenological classifications of experience. This rich ontological landscape is what gives Indian philosophy of mind its distinctive character.*

1 Philosophy of mind in the Upaniṣads

The Upaniṣads viewed the human individual as a composite of psychological and physical elements. Upaniṣadic thinkers set themselves the task of sifting through this psychophysical complexity in the belief that the solution to human suffering lay in some aspect of human existence itself. The urgency and practical nature of this project yielded a rich variety of classificatory schemes as one solution was discarded in favour of another. The Bṛhadāraṇyaka Upaniṣad, for example, distinguishes three generically different types of consciousness in the experiential life of all individuals. The first of these, the waking state, is characterized by pain and pleasure and its content is determined by the external world. It provides the raw materials for the second state, that of dreaming. Dreaming, however, differs from wakefulness, for in dreams we assume a greater power to construct our own worlds. Yet dreaming still subjects us to pain and pleasure and is viewed as a transition to the third state, that of deep sleep. This third state is characterized by serenity and lack of desire, and, being without content, is also a state in which the distinction between subject and object disappears. This Upaniṣadic classification of experience is thus both descriptive and hierarchical, ranking the three states of consciousness against the requirements of what a liberatory state should be. This tripartite division of everyday experience remained common currency in subsequent philosophy of mind but it was discarded as a solution to the problem of endless rebirth into a world of suffering. The Māṇḍūkya Upaniṣad thus extends the threefold classification to a fourfold classification of experience with the addition of a fourth, liberatory, state of consciousness (*turīya*). This fourth state is a specialized state of consciousness which lies beyond the everyday experience of the individual and is attainable only on the basis of yogic techniques developed for that purpose.

Parallel to the phenomenological analysis, the Upaniṣads also analysed the individual in terms of constituent elements. Many such schemes are to be found in the Upaniṣads, but perhaps the most important for later thought is that presented in the Kaṭha Upaniṣad. This uses an image of a horse-drawn chariot to present the human individual as a composite of different elements in a hierarchical relationship to each other. The horses are likened to the senses (*indriya*), the reins to the mind (*manas*), the charioteer to the intellect (*buddhi*), the chariot to the body (*śarīra*), and the passenger riding in the chariot is the Self (*ātman*). Just as a charioteer needs to gain control of his horses using the reins, so too an individual aspiring to liberation must gain control of the senses using the mental disciplines of *yoga*.

Whether it be in positing a fourth state of consciousness, or in viewing the *ātman* as a passenger in the chariot rather than as the charioteer, it is clear that Upaniṣadic thinkers sought to separate the agent of normal phenomenal experience from the transcendental *ātman*. Indeed, the very failure to distinguish between these two selves is at the root of human suffering, and liberation from rebirth demands that the individual ultimately negate and transcend empirical individuality.

Upaniṣadic thought is thus of necessity dualist in nature. If liberation is to enable the individual to transcend the spatiotemporal world, then there must be some aspect of the individual's existence which lies beyond such a world. On the other hand, if liberation is to be attainable, then it must be amenable to individual experience. There is a tension here between the need to keep these two domains apart and the need to bring them together at some point. It was left to later schools of thought to wrestle in a more systematic way with the consequences of this Upaniṣadic worldview. For example, because of its immutability, the *ātman* is not subject to rebirth. This demands an explanation of the precise mechanism of rebirth. What is it that gets reborn? It also makes the very notion of liberation itself fraught with difficulty. Liberation cannot simply be a liberation of the *ātman* because of course the *ātman* must already lie beyond the spatiotemporal world. Who then is liberated and how? The Sāōkhya-Yoga and Advaita Vedānta schools gave particular attention to solving the problems of their Upaniṣadic legacy and, in doing so, needed to address the question of the relationship between the *ātman* and the empirical individual (see Sāōkhya §§2-3, 6; Vedānta §§1-3).

The dualism of Upaniṣadic thought is distinct from the dualism between the mind and the body in Western philosophy. In Cartesian dualism, the two domains that are sharply distinguished are the mental and the physical. While Indian philosophers certainly recognized such a distinction, they were more impressed by what the mental and the physical had in common, namely that they were both thought to be causally conditioned, with cause preceding effect in a regular, predictable way. Indeed, it was the regular, predictable nature of the mind that enabled spiritual practitioners to manipulate it to their desired goal of quiescence, once the causal mechanisms were understood. Later schools of thought, therefore, developed a rich understanding of the empirical workings of the mind. This is seen in the more complex classificatory schemes that Indian philosophers developed. In the later Yoga school, for example, the fourth state of consciousness described in the Māṇḍūkya Upaniṣad becomes a complex of eight different types of meditative experience. The sharpest distinction arising from Upaniṣadic thought occurs in the opposition of the *ātman* to both the mental and the physical, inasmuch as the latter are firmly located in the empirical world.

A second important difference between the Cartesian model of the mind and that developed by orthodox Indian philosophers is the distinction the latter make between the *ātman* and the 'I' given in ordinary experience. As one of the psychophysical elements of the individual, the 'I' is just another temporary causally conditioned aspect of the individual with no ultimate value. Again, it was left to later systems of thought to work out the exact nature of the relationship between the *ātman* and the empirical sense of individuality. In Upaniṣadic and subsequent philosophy of mind, there is no transcendental ego in the Cartesian sense, only a transcendental impersonal Self.

2 Philosophy of mind in early Buddhism

Buddhism inherited and propagated the Upaniṣadic view of the human individual as a composite of psychological and physical elements, and the scholasticism of early Buddhist thought presents us with a huge variety of such classifications. Buddhism, however, abandoned the Upaniṣadic idea of an enduring Self. Indeed, the very purpose of Buddhist classifications was meant to reveal the absence of any such entity. In an early post-canonical Buddhist text, the *Milindapañha (Questions of Milinda)*, the monk Nāgasena prompts King Milinda towards the correct view. Milinda is led, through a series of questions, to realize that the term 'chariot' designates nothing more than a pole, axle, set of wheels, chariot body, banner-staff, goad and pair of reins. Similarly, the term 'Nāgasena' is but a way of designating a collection of ever-changing physical and psychological elements. The passenger who rides in the chariot of the Kaṭha Upaniṣad is here conspicuous by his absence. There is no permanent substratum underlying our existence.

A personal proper name thus refers to a stream of causally connected elements. As Buddhist thought developed, philosophers of all schools presented increasingly detailed and distinctive descriptions and classifications of these elements. Prevalent in these schemas is a broad distinction between those elements that are mental and those that are physical. This is seen in the distinction made in the early Buddhist texts between name (*nāma*) and form

(*rūpa*), and also in the widely influential classification of the elements into five categories (*skandha*). This latter classification, which purported to be an exhaustive description of the elements, divided them into five different types: physical form (*rūpa*), sensation (*vedanā*), conceptualization (*saṃjñā*), dispositions (*saṃskāra*) and consciousness (*vijñāna*). Four of the five categories relate to different types of mental events, indicating the importance of the latter, even though Buddhist philosophers from the different schools understood these categories somewhat differently.

It is important to understand exactly what Buddhists wished to deny with their 'no-self' theory (*anātma-vāda*) and this cannot be done without developing an adequate understanding of the complexity of Buddhist practice and the functions of different types of Buddhist texts. The no-self theory did not prohibit our usual ways of talking about the self in literature of a narrative and ethical nature. Where the theory is important is in the more technical, philosophical literature, where any talk of a permanent Self is prohibited by Buddhist ontology (see Buddhist philosophy, Indian §5; Buddhist concept of emptiness §1). In the great systematic treatises of Buddhism, such as the fifth-century Vaibhāṣika text, the *Abhidharmakośa (Treasury of Metaphysics)*, we see the attempt to construct a comprehensive Buddhist ontology in which the objects of conventional discourse will disappear. Vasubandhu, its author, construes ultimate reality in terms of seventy-five different types of unique, self-sufficient, momentary particulars known as *dharmas* (see Buddhism, Ābhidharmika schools of).

The no-self theory was also important in terms of its influence on meditational practice, since theory and practice were not seen as two separate activities. The Buddhist doctrine itself was an important focus for one type of meditational practice, in which the aim was to augment a mere intellectual understanding of the doctrine with an actual change in the cognitive and perceptual apparatus of the practitioner by internalizing the doctrinal categories of thought. For example, the *dharma* analysis of the Vaibhāṣika system, as well as being an intellectual enterprise, was also linked to meditational practices aimed at deconstructing the categories of everyday experience. The Buddhist rejection of the *ātman* also meant that Buddhism did not equate meditational states of consciousness with the realization of a liberatory Self. Although valuable, meditational states were still causally conditioned, and hence temporary, states of existence. As such, they could not be the final solution to the problem of suffering.

Despite their differences, it should be remembered that Buddhism and Upaniṣadic thought were both responses to a common problem, the suffering of the individual caught up in an endless round of rebirth. Buddhism rejected the idea of an enduring Self largely on the grounds that, as an idea, it was unhelpful in freeing the individual from suffering. Both traditions viewed empirical individuality as problematic. Buddhist philosophers did not frame the no-self theory as a challenge to the idea of rebirth. Rather, they themselves were challenged to address the intellectual problems that arose once these two ideas were brought together. If the theory could not be reconciled with the belief in rebirth, then so much the worse for the no-self theory. As with Upaniṣadic thought, it was left for later systematic philosophy to address some of these questions.

3 Personal identity in Indian philosophy of mind

In the Western analytic tradition, personal identity and the mind-body problem have been central and related questions in the philosophy of mind. In the context of Indian philosophy of mind, parallel questions do arise, but in such a different context that the cross-cultural philosopher cannot make any simple comparisons. Personal identity is largely problematic in Indian philosophy because of the mistaken value individuals attach to it. For both Buddhist and non-Buddhist alike, any account of personal identity must at the same time reveal its lack of absolute value for that individual. This point is especially important for the correct interpretation of karma and rebirth doctrines, which should not necessarily be interpreted as doctrines requiring the personal survival of bodily death. Buddhist philosophers, for example, did have a problem reconciling their no-self view with the belief that actions performed in one life can have repercussions in another, but it was largely a problem of explaining how the past can be causally efficacious in the present. This was not so much a problem of making sense of the notion of moral responsibility in the absence of either bodily or memory continuity, but, rather, was a mechanistic problem of bringing a cause and its temporally distant effect together. This became a particularly intractable problem given the Buddhist metaphysics of constant change and the Buddhist view of consciousness as being intentional in nature. Together these two ideas could lead to the view that an individual is but a flux of events conditioned only by the present. The 'warehouse consciousness' (*ālaya-vijñāna*) posited by the Yogācāra school of Buddhism was one attempt to solve this problem. Although momentary in nature, the warehouse consciousness was nonintentional

and thus provided a locus for ‘karmic seeds’ until they were ripe for maturation (see Buddhism, Yogācāra school of §§6-8).

Some Western philosophers have believed that a sense of self is given directly as a separate content of our experience. The word for ‘I’ in Indian philosophy is *ahaṃkāra*, meaning literally ‘I-maker’. This indicates a view common to both Buddhist and non-Buddhist philosophers, that the ‘I’ is made on the basis of something else. Indian philosophers of mind were interested in discovering how experience gives rise to this sense of ‘I’. The word *ahaṃkāra* also indicates the view that it is through our constant utterances of ‘I’ or ‘this is mine’ that we solidify our sense of empirical individuality. Thus even where non-Buddhist philosophers - for example, in the Advaita Vedānta school - used arguments strikingly similar to the *cogito ergo sum* argument of Descartes, indicating that the self really is a genuine datum of experience, they would want to add that the self given by such an argument is the self of waking consciousness, and hence a necessarily limited self in relation to the *ātman*. Philosophers of the Advaita Vedānta school were concerned to develop an understanding of the relationship between the *ātman* and the self as given in the schema of three generically different kinds of consciousness inherited from the Upaniṣads (waking, dreaming, deep sleep). Some philosophers of the Advaita Vedānta school viewed the empirical self as a distorted reflection of the *ātman*, while others viewed it as the result of limitations being placed upon the *ātman*. Ignorance (*avidyā*) is in each case responsible for the misperception (see Monism, Indian §§1-2).

Buddhist philosophers were resolute in their resistance to converting the sense of ‘I’ given in empirical experience into any kind of theoretical or absolute reality. Consciousness is a changing, conditioned phenomenon and there is no self beyond any given moment of conscious experience. Thus, for example, the *dharma* theory of the Vaibhāṣika tradition was also a meditational technique enabling practitioners to view their experience in impersonal rather than subjective terms.

4 The mental and the physical in Indian philosophy of mind

While Indian philosophers certainly recognized the distinction between the mental and the physical, both phenomenologically and often ontologically, this difference did not become of such overriding importance as it did in Western philosophy of mind. Rather, the different schools of thought focused on the complex task of mapping out the network of causes underlying the occurrence of any individual mental event, which could be the product of a complex which might include both mental and physical causes. Perceptual events, for example, were generally viewed as the result of a causal interaction involving both mental and physical causes. Six sense organs were acknowledged by Indian philosophers, those of vision, hearing, smell, taste, touch and the mind. The mind (*manas*) was classified along with other sense organs and was responsible for inner cognition, as well as being able to coordinate the other sense organs (see Sense perception, Indian views of §§1-2). Where the schools differed in their understanding of perception, it was largely on account of differences in their wider metaphysical beliefs concerning the status of physical objects and the existence of an external world. There would be no uniform response from Indian philosophers to the Lockean proposition that it is impossible to perceive without perceiving that one perceives. This was a point of considerable contention between the different schools. It was agreed, however, that waking consciousness was intentional in nature: being awake meant being awake to something. Despite the many differences between the schools and the complexity of the tradition, Indian philosophers were united in their characterization of consciousness as a complex continuum of causally conditioned mental events fuelled by the inherent restlessness of the human condition. Their need to understand the principles governing this continuum lay at the heart of Indian philosophy of mind.

Mind, philosophy of

'Philosophy of mind', and 'philosophy of psychology' are two terms for the same general area of philosophical inquiry: the nature of mental phenomena and their connection with behaviour and, in more recent discussions, the brain.

Much work in this area reflects a revolution in psychology that began mid-century. Before then, largely in reaction to traditional claims about the mind being non-physical (see Dualism; Descartes), many thought that a scientific psychology should avoid talk of 'private' mental states. Investigation of such states had seemed to be based on unreliable introspection (see Introspection, psychology of), not subject to independent checking (see Private language argument), and to invite dubious ideas of telepathy (see Parapsychology). Consequently, psychologists like B.F. Skinner and J.B. Watson, and philosophers like W.V. Quine and Gilbert Ryle argued that scientific psychology should confine itself to studying publicly observable relations between stimuli and responses (see Behaviourism, methodological and scientific; Behaviourism, analytic).

However, in the late 1950s, several developments began to change all this: (i) The experiments behaviourists themselves ran on animals tended to refute behaviouristic hypotheses, suggesting that the behaviour of even rats had to be understood in terms of mental states (see Learning; Animal language and thought). (ii) The linguist Noam Chomsky drew attention to the surprising complexity of the natural languages that children effortlessly learn, and proposed ways of explaining this complexity in terms of largely unconscious mental phenomena. (iii) The revolutionary work of Alan Turing (see Turing machines) led to the development of the modern digital computer. This seemed to offer the prospect of creating Artificial intelligence, and also of providing empirically testable models of intelligent processes in both humans and animals. (iv) Philosophers came to appreciate the virtues of realism, as opposed to instrumentalism, about theoretical entities in general.

1 Functionalism and the computational theory of mind

These developments led to the emergence in the 1970s of the loose federation of disciplines called 'cognitive science', which brought together research from, for example, psychology, linguistics, computer science, neuroscience and a number of sub-areas of philosophy, such as logic, the philosophy of language, and action theory. In philosophy of mind, these developments led to Functionalism, according to which mental states are to be characterized in terms of relations they bear among themselves and to inputs and outputs, for example, mediating perception and action in the way that belief and desire characteristically seem to do. The traditional problem of Other minds then became an exercise in inferring from behaviour to the nature of internal causal intermediaries.

This focus on functional organization brought with it the possibility of multiple realizations: if all that is essential to mental states are the roles they play in a system, then, in principle, mental states, and so minds, could be composed of (or 'realized' by) different substances: some minds might be carbon-based like ours, some might be computer 'brains' in robots of the future, and some might be silicon-based, as in some science fiction stories about 'Martians'. These differences might also cause the minds to be organized in different ways at different levels, an idea that has encouraged the co-existence of the many different disciplines of cognitive science, each studying the mind at often different levels of explanation.

Functionalism has played an important role in debates over the metaphysics of mind. Some see it as a way of avoiding Dualism and arguing for a version of materialism known as the identity theory of mind (see Mind, identity theory of). They argue that if mental states play distinctive functional roles, to identify mental states we simply need to find the states that play those roles, which are, almost certainly, various states of the brain. Here we must distinguish identifying mental state tokens with brain state tokens, from identifying mental types with brain types (see Type/token distinction). Many argue that multiple realizability shows it would be a mistake to identify any particular kind or type of mental phenomenon with a specific type of physical phenomenon (for example, depression with the depletion of norepinepherine in a certain area of the brain). For if depression is a multiply realized functional state, then it will not be identical with any particular type of physical phenomenon: different instances, or tokens, of depression might be identical with tokens of ever different types of physical phenomena (norepinephrine deletion in humans, too little silicon activation in a Martian). Indeed, a functionalist could allow (although few take this seriously) that there might be ghosts who realize the right functional organization in some

special dualistic substance. However, some identity theorists insist that at least some mental state types - they often focus on states like pain and the taste of pineapple, states with Qualia (see also the discussion below) - ought to be identified with particular brain state types, in somewhat the way that lightning is identified with electrical discharge, or water with H_2O. They typically think of these identifications as necessary a posteriori.

An important example of a functionalist theory, one that has come to dominate much research in cognitive science, is the computational theory of mind (see Mind, computational theories of), according to which mental states are either identified with, or closely linked to, the computational states of a computer. There have been three main versions of this theory, corresponding to three main proposals about the mind's Cognitive architecture. According to the 'classical' theory, particularly associated with Jerry Fodor, the computations take place over representations that possess the kind of logical, syntactic structure captured in standard logical form: representations in a so-called Language of thought, encoded in our brains. A second proposal, sometimes inspired by F.P. Ramsey's view that beliefs are maps by which we steer (see Belief), emphasizes the possible role in reasoning of maps and mental Imagery. A third, recently much-discussed proposal is Connectionism, which denies that there are any structured representations at all: the mind/brain consists rather of a vast network of nodes whose different and variable excitation levels explain intelligent Learning. This approach has aroused interest especially among those wary of positing much 'hidden' mental structure not evident in ordinary behaviour (see Ludwig Wittgenstein §3 and Daniel Dennett).

The areas that lend themselves most naturally to a computational theory are those associated with logic, common sense and practical reasoning, and natural language syntax (see Common-sense reasoning, theories of; Rationality, practical; Syntax); and research on these topics in psychology and Artificial intelligence has become deeply intertwined with philosophy (see Rationality of belief; Semantics; Language, philosophy of).

A particularly fruitful application of computational theories has been to Vision. Early work in Gestalt psychology uncovered a number of striking perceptual illusions that demonstrated ways in which the mind structures perceptual experience, and the pioneering work of the psychologist, David Marr, suggested that we might capture these structuring effects computationally. The idea that perception was highly cognitive, along with the functionalist picture that specifies a mental state by its place in a network, led many to holistic conceptions of mind and meaning, according to which parts of a person's thought and experience cannot be understood apart from the person's entire cognitive system (see Holism: mental and semantic; Semantics, conceptual role).

However, this view has been challenged recently by work of Jerry Fodor. He has argued that perceptual systems are 'modules', whose processing is 'informationally encapsulated' and hence isolatable from the effects of the states of the central cognitive system (see Modularity of mind). He has also proposed accounts of meaning that treat it as a local (or 'atomistic') property to be understood in terms of certain kinds of causal dependence between states of the brain and the world (see Semantics, informational). Others have argued further that Perception, although contentful, is also importantly non-conceptual, as when one sees a square shape as a diamond but is unable to say wherein the essential difference between a square and a diamond shape consists (see Content, non-conceptual).

2 Mind and meaning

As these last issues indicate, any theory of the mind must face the hard topic of meaning (see Semantics). In the philosophies of mind and psychology, the issue is not primarily the meanings of expressions in natural language, but of how a state of the mind or brain can have meaning or content: what is it to believe, for example, that snow is white or hope that you will win. These latter states are examples of Propositional attitudes: attitudes towards propositions such as that snow is white, or that you will win, that form the 'content' of the state of belief or hope. They raise the general issue of Intentionality, or how a mental state can be about things (for example, snow) and properties (for example, white), and, particularly, 'about' things that do not exist or will not happen, as when someone believes in Santa Claus or hopes in vain for victory.

There have been three main proposals about mental content. A state might possess a specific content: (i) by virtue of the role it plays in reasoning (see Semantics: conceptual role); (ii) by virtue of certain causal and lawful relations the state bears to phenomena in the world (see Semantics: informational; Functionalism); or (iii) by virtue of the function it plays in the evolution and biology of the organism (see Semantics: teleological; Functional

explanation). Related to these proposals are traditional philosophical interests in Concepts, although this latter topic raises complicating metaphysical concerns with Universals, and epistemological concerns with A priori knowledge.

Special problems are raised by indexical content, or the content of thoughts involving concepts expressed by, for example, 'I myself', 'here', 'now', 'this', and 'that' (see Content, indexical; Demonstratives and indexicals; Propositional attitudes §3). Does the thought that it is hot here, had in Maryland, have the same content as the thought that it is hot here, had in Canberra? The conditions under which such thoughts are true obviously depends upon the external context - for example, the time and place - of the thinking.

This dependence on external context is thought by many to be a pervasive feature of content. Drawing on recent work on reference (see Reference; Proper names), Hilary Putnam and Tyler Burge have argued that what people think, believe and so on depends not only on how they are, but also upon features of their physical and social environment. This raises the important question of whether an organism's psychology can be understood in isolation from the external world it inhabits. Defenders of methodological individualism insist that it can be (see Methodological individualism); Putnam, Burge and their supporters that it can't. Some theorists respond to the debate by distinguishing between wide and narrow content: narrow content is what 'from the skin in' identical individuals would share across different environments, whereas wide content might vary from one environment to the next (see Content: wide and narrow). These theorists then give distinctive roles to the two notions in theoretical psychology, although this is a matter of great controversy.

3 Alternatives to functionalism

Not everyone endorses functional and computational theories of mind. Some, influenced by Ryle and the later Wittgenstein, think that such concern with literally inner processes of the brain betrays a fundamental misunderstanding of mental talk, which, they argue, rests largely on outward Criteria. Others think that computational processes lack the means of capturing the basic properties of Consciousness and Intentionality that are essential to most mental phenomena. John Searle, in particular, regards his Chinese room argument as a devastating objection to computational approaches. He thinks that mental phenomena should be understood not functionally, but directly in biological or physical terms.

The hardest challenge for functionalism is posed by Qualia - the properties that distinguish pain, the look of red, the taste of pineapple, and so on, on the one hand, from mental states like belief and understanding on the other. (See also Bodily sensations; Sense-data; Perception). Some argue that unnecessary problems are produced in this area by an excessive reification of inner experience, and recommend instead an adverbial theory of mental states (see Mental states, adverbial theory of). However, some problems persist, and can be made vivid by considering the possibility of 'inverted qualia'. It seems that two people might have colour experiences that are the complements of one another (red for green, yellow for blue, etc.), even though their behaviour and functional organization are identical. This issue is explored in Colour and qualia and leads inevitably to the hard problems of Consciousness: What is it? What things have it? How do we tell? What causal role, if any, does it play the world?

There is also an issue for functionalists over Mental causation. A principal reason why Dualism has few adherents today is the problem of explaining how non-physical or non-natural phenomena can causally affect a physical world. And although some dualists retreat to Epiphenomenalism, the view that mental phenomena are caused by, but do not themselves cause any physical phenomena, this is widely seen as implausible. However, functionalists also have a problem. Even though they can and do insist that functional states are realized physically, arguably the functional states *per se* do no causing; what does the causing would seem to be the underlying physical properties of the physical realization. So, although functionalists avoid giving causal roles to the 'non-natural', it seems they must allow that mental properties *per se* do no causing.

Although the view that the mind is a natural phenomenon is now widely accepted (principally because of the causal problem for dualism), what this implies is highly contentious. Some hold that it simply means that mental phenomena supervene on physical nature in the sense that there can be no mental difference without a physical difference (see Supervenience of the mental). Donald Davidson thinks this can be true without there being any strict laws connecting the physical and the mental (see Anomalous monism). Others insist that a naturalist about the mind must reduce the mental to the physical in somewhat the way thermodynamics has been reduced to

statistical mechanics, so delivering neat lawful biconditionals linking the mental and the physical (see Reductionism in the philosophy of mind).

Much in this discussion turns on the status of Folk psychology, the theory of mind allegedly implicit in ordinary (folk) thought and talk about the mind. On one view, mental states are simply the states that fill the roles of this implicit theory, and the reduction consists in finding which internal physical states fill the roles and are, thereby, to be identified with the relevant mental states. However, defenders of Eliminativism, noting that any theory - especially a folk one - can turn out false, argue that we should take seriously the possibility that the mental states postulated by folk psychology do not exist, much as it turned out that there are no witches or phlogiston.

4 Issues in empirical psychology

Empirical psychology has figured in philosophy not only because its foundations have been discussed in the above ways, but also because some of its specific findings have been relevant to traditional philosophical claims. Thus, experiments on Split brains have undermined traditional conceptions of Personal identity (see also Mind, bundle theory of), and research on the reliability of people's self-attribution of psychological states has cast doubts on introspection as a source of specially privileged knowledge about the mind. The work of Freud on psychopathology (see Mental illness, concept of; Psychoanalysis, post-Freudian; Psychoanalysis, methodological issues in) and of Chomsky in linguistics, suggests that the states of most explanatory interest are not introspectively accessible (see Knowledge, tacit; Unconscious mental states). Chomsky's ideas also seem to revive Rationalism's postulation of innate knowledge that was long thought to have been discredited by Empiricism (see also Nativism; Innate knowledge; Language, innateness of). And they have stimulated research beyond knowledge of grammar, into infant cognition (see Cognition, infant) generally (some of which treats the Molyneux problem of whether newly sighted people would be able to recognize shapes that they had previously only touched). Other questions about the basic categories in which people understand the world have benefited from work on how these categories are understood and evolve in childhood (see Piaget, J.; Cognitive development; Moral development). A particularly important issue for the philosophy of mind concerns the origin of our mental concepts, a topic of lively current research (see Mind, child's theory of) that affects our understanding of Folk psychology.

5 Philosophy of action

Whether or not it is ultimately vindicated by empirical research, folk psychology is a rich fund of distinctions that are important in human life. The examination of them has tended to focus on issues in the explanation of Action, and, in a related vein, on psychological issues relevant to ethics (see Moral psychology).

The traditional view of action, most famously advocated by David Hume, is that an action needs both a desire and a belief. The desire provides the goal, and the belief the means of putatively achieving it (see also Reasons and causes; Desire; Belief). But what then is the role, if any, of Intention? Are intentions nothing more than some complex of belief and desire? And how, if at all, do we find a place in the Humean picture for the will? Is it something that can somehow act independently of beliefs and desires, or is it some kind of manifestation of them, some kind of 'all things considered' judgment that takes a person from dithering to action? (See Will, the.) Notoriously difficult questions in this regard concern whether there actually is anything as Free will, and how it is possible for a person to act against their better judgement, as they seem to do in cases of Akrasia, or 'weakness of will'.

Beliefs and desires seem intimately connected with many other mental states. Belief about the past is of the essence of Memory. Perception delivers belief about how things are around one, and Dreaming seems to be the having of experiences during sleep akin to (rather fragmented) perceptions in the way they tend to make you believe that certain things are happening. Even emotions and bodily sensations seem to have belief and desire components (see Emotions, nature of; Bodily sensations): anger involves both a belief that one has been wronged and a desire to do something about it, and pain involves the belief that something is amiss and the desire that it stop. Much contemporary philosophy of mind and action is concerned with teasing out the relationship between beliefs and desires and various other mental states, although approaches in cognitive science often focus upon more computationally active states, such as: noticing, deciding, and 'on line' processes of reasoning.

Mir Damad, Muhammad Baqir (d. 1631)

Mir Damad is primarily a gnostic philosopher, arguing that the activity of the mind makes possible the experience of spiritual visions, while visionary experience gives rise to rational thought. He brings together a variety of different traditions in Islamic philosophy, incorporating both the sort of philosophy advocated by Aristotle and its later development by the Neoplatonists, and combining them with the mystical views of Islamic thinkers. The principles of his thought are the backbone of the celebrated 'School of Isfahan', which developed this rich mixture of philosophical traditions even further. His approach to the analysis of being was a considerable extension to previous views on this subject, and enabled him to make important contributions to the notion of time. Mir Damad's philosophical style is characterized by a treatment of abstract concepts behind which lies the living experience of the mystic.

1 Life and philosophy of being

Mir Burhan al-Din Muhammad Baqir Damad, whose poetic *nom de plume* was 'Ishraq' and who was also referred to as 'the Third Master' (after Aristotle and al-Farabi) was born into a distinguished religious family. Another honorific title by which Mir Damad has been known is Sayyid al-Afadil, 'Prince of the Most Learned'.

Mir Damad was born in Astarabad but grew up in Mashhad, the religious capital of Shi'i Persia. He received his early education there, and studied Ibn Sina's texts closely (see Ibn Sina). Prior to coming to Isfahan during the reign of Shah 'Abbas, he also spent some time in Qazvin and Kashan. In Isfahan, Mir Damad continued his education, paying equal attention to rational and transmitted sciences. He died in AH 1041/AD 1631 when he fell ill on his way to Karbala, in the entourage of Shah Safi. He was buried in Najaf.

As is evident from his contemporary sources, Mir Damad was recognized simultaneously as a jurist, a mystic and a philosopher - a rare but not altogether impossible combination in Muslim intellectual history. His writings reflect his comprehensive and encyclopedic interests. He wrote on philosophy and theology, prophetic and Imami traditions, Shi'i law, Qur'anic commentary, ethics and mysticism as well as on logic. Mir Damad's ascetic exercises have been noted particularly by some of his biographers (see the introduction to the 1977 edition of *Kitab al-qabasat (Book of Embers)*, page xxviii). These exercises are combined, if his biographers' sometimes hyperbolic tone is to be believed, with a precocious attention to philosophy.

Despite his prominent status as both a mystic and a jurist, an uneasy combination made possible by certain specific features of the School of Isfahan, it was principally as a philosopher that Mir Damad recognized, praised and distinguished himself, as in his many self-praising poems, for example:

> I conquered the lands of knowledge, I lent old wisdom to my youth. So that I made the earth with my *al-Qabasat* The envy of the heavenly abodes
>
> (Hadi 1984: 134)

Al-Qabasat is Mir Damad's most significant philosophical work, containing the essence of his philosophy. *Al-Qabasat* consists of ten *qabas* ('a spark of fire') and three conclusions. Its central question is the creation of the world and the possibility of its extension from God. The first *qabas* discusses the variety of created beings and the divisions of existence. In the second he argues for a trilateral typology of essential primary notions and the primacy of essence. The duality of perspectives through which essence is subdivided and an argument to that effect through pre-eternal principles constitutes the third *qabas*. In the fourth, Mir Damad provides Qur'anic evidence, as well as references from the Prophetic and Imami traditions, to support his preceding arguments. The fifth *qabas* is devoted to a discussion of the primary dispositions through an understanding of natural existence. The connection (*ittisal'*) between 'time' and 'motion' is the subject of the sixth, where Mir Damad also argues for a 'natural order' in time. Here too he argues for the finality of numeral order and against the infinity of numbers in time-bound events (*al-hawadith al-zamaniyya*). He then devotes the seventh *qabas* to a refutation of opposing views. In the eighth, he verifies the divine authority in the establishment of such orders and the role of reason in ascertaining this truth. The ninth proves the archetypal substance of intellect (*al-jawahar al-'aqliyya*); in this chapter also, Mir Damad argues for the existence of an order in existence, a cycle of beginning and return. Finally, in the tenth *qabas*, he discusses the matter of divine ordination (*al-qada' wa al-qadar*), the necessity of

supplication, the promise of God’s reward, and the final return of all things to his judgment.

In *al-Qabasat*, Mir Damad engages in the age-old debate over the priority of ‘essence’ (*mahiyya*) versus that of ‘existence’ (*wujud*). He ultimately decides on the priority of essence, a position that would later be fundamentally disputed by his distinguished pupil Mulla Sadra. *Al-Qabasat* has remained a central text of Islamic philosophy since its first appearance. A number of philosophers of later generations have written commentaries about it, including Mulla Shamsa Gilani and Aqa Jani Mazandarani (Ashtiyani 1972). Mir Damad wrote *al-Qabasat* in response to one of his students, who had asked him to write a treatise proving that the Creator of creation and being is unique in his pre-eternality, pre-eternal in his continuity, continuous in his everlastingness, and everlasting in his post-eternality. In this text, therefore, he set himself to prove that all existent beings, from archetypal models to material manifestations, are ‘contingent upon nothingness’ (*masbuqun bi’l-‘adam*), ‘inclined towards creation’ (*tarifan bi’l-huduth*), ‘pending on annihilation’ (*marhunun bi’l-halak*), and ‘subject to cancellation’ (*mamnuwwun bi’l-butlan*) (*Kitab al-qabasat*: 1). The question of the pre-eternity (*qidam*) or createdness (*huduth*) of the world is one of the oldest and most enduring questions of Islamic philosophy, deeply rooted in the early Mu‘tazilite codification of Islamic theology (Watt 1962: 58-71; Fakhry 1983: 67-8; Leaman 1985: 11-12, 132-4). Mir Damad reminds his readers that even Ibn Sina considered the debate on this question to be ‘dialectical’ (*jadali*) rather than based on ‘proof’ (*burhan*).

For Mir Damad, being is circulated through a cycle of emanation from the divine presence to the physical world and then a return to it. In a progression of distancing emanations, the material world gradually emanates from the divine presence. From the Light of Lights (*nur al-‘anwar*) first emanate the archetypal lights (*‘anwar qahira*), of which the Universal Intellect (*‘aql-i kull*) is the first component. From this stage emanate the ‘heavenly souls’ (*nufus-i falakhyya*), the ‘ruling lights’ (*‘anwar-i mudabbira*), of which the ‘universal souls’ (*nafs-i kull*) is the primary member. The ‘natural souls’ (*nufus-i muntabi‘a*) were subsequently created by the ‘universal soul’. The archetypes of the heavens, planets, elements, compounds and the four natures were thus created. The final stage of this ontological emanation of being is the creation of matter from these archetypal origins. There is then a reverse order through which matter is sublimated back to light. Through this order, absolute or irreducible body (*jism-i mutlaq*) is advanced to the mineral stage of compound compositions. The minerals are then sublimated to the vegetative stage and then upward to the animal. Man is the highest stage of this upward mobility before the absolute matter rejoins the Light of Lights.

‘Creation’ (*ibda‘*) is the ‘bringing into being’ of something from absolute-nothing. That which is ‘evident’ (*ma’lum*), if left to its own ‘essence’ (*dhat*), would not be. It is only by virtue of something outside it (in other words, its cause) that it is or, more accurately, is brought into being. Things in their own essence have an essential, not a temporal, primacy over things that are located outside of them, such as their cause for becoming evident and manifest. Thus the secondariness of the caused over the primacy of its cause is an essential, not a temporal, secondariness. From this it follows that unless the relation between the cause and the caused is a temporal one, not every caused is created in time, that is, not every *ma‘lul* (caused) is a *muhaddath* (created-in-time). Only that caused is created-in-time which is contingent upon time (*zaman*), motion (*haraka*), and change (*taghayyur*) (*Kitab al-qabasat*: 3). That created-being which is not subsequent to time is either subsequent to absolute nothingness, whose creation is called *ibda‘* (or ‘brought into beginning’), or subsequent to not-absolute-nothingness, in which case its creation is called *ihdath* (or ‘brought into being in time’). If the created being is subsequent to time, it can have only one possibility, which is its being-in-time subsequent to its being-in-nothingness (*Kitab al-qabasat*: 3-4) (see Causality and necessity in Islamic thought).

2 Philosophy of time

There is also a hierarchical conception of time that Mir Damad begins to develop, mostly from arguments used by Ibn Sina, Nasir-i Khusrow and Khwajah Nasir Al-Tusi. First there is time (*zaman*), superior and more expansive than which is the atemporal (*dahr*) and ultimately the everlasting (*sarmad*). This hierarchy of timespan is also to be understood in terms of relationship. *Sarmad* postulates the relation of the permanent to the permanent; *dahr*, the relation of the permanent to the changing; and *zaman*, a relation of the changing to the changing. From this trilateral conception of time, Mir Damad reaches for his unique understanding of creation. Both *huduth* (creation) and *qidam* (pre-eternity) are of three kinds; *dhati* (essential), *dahri* (atemporal), and *zamani* (temporal). Essential pre-eternality (the counterpart of the essential createdness) is that whose being and actuality is not subsequential to

its not-being (*laysiyya*) and/or nothingness (*'adam*). Atemporal pre-eternality (the counterpart of the atemporal createdness) is that whose being and actuality are not subsequential to its absolute nothingness in the span of the atemporal. On the contrary, from pre-eternity it is in-being. Finally, temporal pre-eternity (the counterpart of temporal createdness) is that temporal thing whose being is not specific to a time and whose already-being (*husul*) is constantly present in the course of all time, and of whose being has no temporal beginning.

As a believing Muslim, Mir Damad must accept the createdness of being. Neither essential createdness (*al-huduth al-dhati*) nor temporal createdness (*al-huduth al-zamani*) is subject to disagreement among philosophers because they are self-evident. It is only over the question of atemporal createdness (*al-huduth al-dahri*) that disagreement arises. God's creation of the universe, Mir Damad concludes, is of the *ibda'* (brought into beginning) and *sun'* (brought into createdness) kind as it pertains to atemporal createdness and of the *ihdath* (brought into being in time) and *takwin* (brought into existence) kind as it pertains to temporal createdness.

Mir Damad proceeds to distinguish between three kinds of 'worlds'. First is the Everlasting World (*al-'alam al-sarmadi*), which is the space for Divine Presence, his essence and attributes; second is the Atemporal World (*al-'alam al-dahri*), which is the space for the pure archetypes (*al-mujarradat*); and third is the Temporal World (*al-'alam al-zamani*), which is the space for daily events, created beings and generation and corruption. There is a hierarchical relationship among these three worlds: the Everlasting World encompasses the Atemporal and the Temporal. The Temporal World is the weakest and least enduring of the three.

As temporal events are contingent upon time - that is, there are times when they are not and then they are 'produced', or brought into being, in time - the same contingency governs the hierarchical order of *sarmad* (everlasting), *dahr* (atemporality) and *zaman* (temporality). Every inferior stage, such as *zaman*, is in actual state of non-being to its superior state, in this case *dahr*. The real existence of the superior stage is identical to the actual non-being of the inferior stage. Reversing the order, the accidental defectiveness of the inferior stage - *zaman* to *dahr*, or *dahr* to *sarmad* - is not present in the superior stage. In other words, the in-itself existence of the superior stage is the *ipso facto* non-existence of the inferior stage in-itself. Mir Damad then concludes that the contingent non-being of the world of the archetypals of the *dahri* stage in the stage of *sarmadi* existence is a real and self-evident non-being. Thus all created beings and their archetypals are consequent to real and self-evident non-being. Their creation is an atemporal (*dahri*) creation and not, as theologians maintain, a temporal (*zamani*) creation. From this it follows that beyond their essential creation (*al-huduth al-dhati*), all temporal events are contingent upon and consequent to three real modes of non-existence: temporal, atemporal and everlasting. All the archetypal beings in the stage of temporal being are also contingent upon and consequent to one kind of non-being, namely the everlasting; and, of course, the everlasting world is not contingent upon or consequential to anything.

What Mir Damad achieves through this systematic separation of a trilateral stipulation of existence is the effective isolation of God at the top of the hierarchy, where he can initiate and sustain the world and yet not be subsequent to temporal corruption, to which all visible creations must yield. Moreover, the necessary contingency of an agent of creation, which is evidently active in the *zamani* and *dahri* stages of existence, is not necessary in the superior stage of *sarmadi*. As one commentator rightly observes, 'by devising the concept of *huduth-i dahri* (atemporal creation), he has succeeded in establishing a compromise between the theologian and the philosopher, in other words, between the religious law and reason' (Musawi Bihbahani in introduction to 1977 edition of *Kitab al-qabasat*: lxix).

3 Philosophical style

Mir Damad's philosophical discourse is indexical and suggestive, symbolic and referential. He relies heavily on a thorough knowledge of previous Islamic philosophy, and has a particular penchant for obscure Arabic words. The legendary difficulty of his philosophical prose should be understood as a response to the anti-philosophical climate of the period promoted by the politically powerful nomocentric jurists. Perhaps the greatest philosopher of this period, Mulla Sadra, was forced to leave the capital city of Isfahan at the instigation of the high clerical establishment precisely because of the articulate clarity of his writing. A story in *Qisas al-'ulama* is illustrative: Mulla Sadra saw Mir Damad in a dream and asked why people condemned him as a blasphemer when he had just repeated what Mir Damad had already said. 'The reason is', Mir Damad answered, 'that I wrote about philosophical matters in such a way that the religious authorities (*'ulama*) could not understand them, and that nobody other than philosophers would comprehend them. But you have vulgarized the philosophical issues and

expounded them in such a way that a teacher at an elementary religious school can understand them. That is why they have called you a blasphemer and not me' (Tunikabuni 1985: 334-5).

Miracles

Does God at times miraculously intervene in earthly affairs? That is, do some events occur because God has entered our space-time continuum and directly modified or circumvented the relevant natural laws? Few philosophers today deny that this is possible. But many question whether we could ever justifiably maintain that such intervention has taken place.

According to some philosophers, it is not even necessary to grant that the types of events believers label miracles - for instance, healings or resurrections - actually occur as reported. Since the evidence supporting the occurrence of such events is the personal testimony of a few, possibly biased, individuals, while the basis for doubt is the massive amount of objective research upon which the relevant laws are based, it is always justifiable, according to this view, to conclude that such reports are erroneous. Others contend, however, that the presence of some forms of evidence - for instance, independent confirmation from reputable sources - could make it most reasonable in some cases to acknowledge that even the most unexpected of events had actually occurred.

Some philosophers also deny that we could ever justifiably conclude that an event could not have been produced by natural causes alone. Since we will never be in a position to identify all that nature can produce, they declare, it will always be most reasonable for the scientist facing a currently unexplainable counterinstance to a natural law to continue to look for a natural explanation. Many believers, however, are quite willing to grant that nature could in principle produce any event, since what they wish to maintain is only that nature does not do so in the case of miraculous interventions.

Finally, while many philosophers acknowledge that belief in direct divine intervention may at times be justifiable for those who already believe that God exists, some also argue that no single event or series of events could ever compel all thoughtful individuals to acknowledge the existence of a perfectly good supernatural causal agent, given all we experience - for instance, the tremendous amount of horrific evil in our world. Many believers, though, are also willing to grant this point.

1 Definition

The term 'miracle' is sometimes used in ordinary discussions to refer to the occurrence of any unexpected event - from the sudden discovery of a lost possession to the unanticipated passing of an exam. Within philosophical circles, however, 'miracle' is almost always discussed in its more restricted sense: as a designation for an unusual event that is the result of direct divine circumvention or modification of the natural order.

Philosophers, as well as religious believers, differ on the exact nature of the conceptual relationship between miraculous divine interventions and the natural order. For those who understand miracles to be violations of natural laws, a miracle is not simply an event that nature *did* not alone produce. It is an event that nature *could* not have produced on its own - an event that will always be incompatible with the relevant natural laws (see Laws, natural). For example, as proponents of the violation model understand it, to maintain that someone has miraculously been healed, it is not sufficient to maintain simply that God was directly involved. It is also necessary to maintain that the state of affairs in question could not have occurred naturally (that no totally natural explanation could be forthcoming).

Other philosophers, and many believers, however, deny that a miraculous divine intervention must be defined as an event for which no plausible natural explanation is, or could be, available. It is sufficient, they believe, to maintain that God was directly involved. For example, to maintain that someone's cancer has miraculously entered remission, it is not necessary to hold that nature alone could not have brought it about (to maintain that it could not have happened naturally). It is sufficient to maintain that nature alone did not do so in this case.

2 The possibility of miracles

Some philosophers (for example, McKinnon 1967) have claimed that the concept of a miracle, if defined as a violation of a natural law, is incoherent. Natural laws, they point out, are really only generalized descriptions of what does in fact happen. That is, these laws summarize for us the actual course of events. Accordingly, to claim that an occurrence is a violation of a natural law is to claim that the event in question is a suspension of the actual

course of events and this is, of course, impossible. Events may well occur, they acknowledge, that seem at present to be incompatible with how we believe things normally happen. But a true counterinstance to what we now believe to be a natural law only shows the law to be inadequate. Since natural laws, by definition, only summarize what actually occurs, we must always be willing in principle to expand our laws to accommodate any occurrence, no matter how unusual. We can never have both the exception and the rule.

Others, however, take this line of reasoning to be based on a confusion. To maintain that a natural law accurately describes the natural order, they point out, is to say only that it correctly identifies that which will occur under a specific set of natural conditions. But to maintain that an event is a miraculous counterinstance to a natural law is not to maintain that some event has occurred under the exact set of natural conditions covered by this law and nothing more. To say that water has miraculously turned into wine, for example, is not to say that water has turned into wine only under the exact set of natural conditions under which the relevant laws tell us this will not occur. It is to maintain that an additional non-natural causal factor, namely direct divine activity, was also present in this case. Accordingly, these philosophers contend, unless it is assumed that supernatural activity is impossible, it cannot be assumed that a miraculous counterinstance to a natural law - a counterinstance produced in part by divine circumvention or modification of the natural order - is conceptually impossible. That is, unless it is assumed that supernatural intervention is impossible, we can have both the exception and the rule.

Of course, many individuals do in fact deny the existence of any type of supernatural being. And even some who affirm the existence of such a being - for example, process theists (see Process theism) - deny that this being can unilaterally intervene in earthly affairs in the sense necessary to produce miraculous events. However, few philosophers today maintain that the existence of a supernatural being, or the ability of such a being (if it exists) to intervene, can be demonstrated to be impossible. That is, while most philosophers agree that the existence of a supernatural being who intervenes in earthly affairs can justifiably be denied, most also agree that it is possible to maintain justifiably that such a being does exist. Consequently, few deny that miracles, even if defined as violations of natural laws, could occur. Since the time of David Hume (§2), however, philosophers have continued to debate vigorously a number of questions related to our ability to *identify* miraculous events.

3 The credibility of personal testimony

One such question is whether we need even acknowledge that alleged counterinstances to well-confirmed natural laws actually occur. Most philosophers agree that reports of repeatable counterinstances - counterinstances that can in principle be produced by anyone under a specified set of natural conditions - cannot justifiably be dismissed. But there are a number of philosophers (most notably Flew 1961) who believe that if the events in question are nonrepeatable - if they cannot be reproduced under specifiable natural conditions - the situation is quite different. It is clearly possible, they acknowledge, that nonrepeatable counterinstances to well-confirmed natural laws have occurred (or will occur). They acknowledge, for instance, that nonrepeatable counterinstances to our current laws describing the properties of water or human tissue may have occurred (or might occur). However, the evidence supporting the adequacy of laws of this type, they point out, is very strong. These laws not only can be, but are, tested and reconfirmed daily by people with no vested interest in the outcome.

On the other hand, they are quick to add, reports of presently nonrepeatable counterinstances to such laws - a claim, for instance, that water has turned into wine or that someone has been raised from the dead - will be supported at best only by the personal testimony of a few people who may well have a vested interest in the outcome. Consequently, as long as alleged counterinstances remain nonrepeatable, we can never possess better reasons for believing that the events in question have actually occurred as reported than for believing that they have not. And therefore, following the Humean maxim that the wise person proportions belief to the evidence, these philosophers conclude that it is always justifiable to deny the accuracy of such reports.

However, there are those (for instance, Swinburne 1967) who believe that this conclusion is much too strong. They acknowledge that reports of seemingly nonrepeatable counterinstances to well-established laws must be approached with appropriate scepticism, since deception or misperception is always possible. But from their perspective it is unreasonable to assume that the evidence supporting even the most highly confirmed laws would *always* furnish a sufficient basis for dismissing reports of counterinstances to them.

First and foremost, they argue that to make this assumption fails to take into account the *prima facie* reliability of

our visual belief-forming faculties. We all rely on these faculties daily and, in general, they serve us quite well. In fact, the general reliability of such faculties must be presupposed by those formulating our natural laws. Thus, in cases where we had no reason to doubt the reliability of these belief-forming faculties - for instance, if we were to observe a seeming counterinstance ourselves or if it were directly observed by a friend whose character and objectivity were beyond question - it is not clear, they maintain, that it would always be justifiable to decide in favour of the natural laws in question, even if they were very well established.

Moreover, these philosophers add, we might in some cases have compelling physical traces to consider. In the case of an alleged healing that runs counter to well-established laws, for instance, we might have more than personal testimony. We might have objective data - photographs or videotapes or X-rays or medical records - that would stand as strong evidence for the occurrence of the event in question, evidence so convincing that it would be unreasonable to reject it. Thus they conclude that decisions concerning the accuracy of reports of alleged counterinstances - even if the events in question are nonrepeatable - must be made on a case-by-case basis.

4 Miracles as events unexplainable by natural causes

Even if some occurrences can justifiably be labelled counterinstances to our current laws, could we ever be in a position to maintain justifiably that any such event is permanently unexplainable scientifically? That is, could we ever be in a position to maintain that an acknowledged counterinstance is a state of affairs that nature could never produce on its own?

In addressing this question, it is important to clarify a potential ambiguity that has been glossed over so far in this entry. By definition, no specific state of affairs produced even in part by direct supernatural activity (by direct circumvention or modification of the natural cause/effect patterns) could ever be given a totally natural explanation. Accordingly, if we were ever in a position to maintain justifiably that some event was actually a direct act of God, we would automatically be in a position to maintain justifiably that this specific occurrence was, itself, permanently unexplainable scientifically.

As currently understood by most philosophers, however, the primary purpose of natural science is not to determine what nature has in fact produced. The main objective of science, rather, is to determine what nature is capable of producing - what can occur under solely natural conditions. For instance, the primary purpose of natural science is not to determine whether natural factors alone actually did cause any specific person's cancer to enter remission. The primary purpose of science is to determine whether natural factors alone could have done so.

Hence, when philosophers ask whether we could ever be in a position to maintain justifiably that an event is permanently unexplainable scientifically, they are not asking whether we could ever be in a position to maintain justifiably that a specific state of affairs *was* not produced by nature alone. They are asking, rather, whether we could ever be in a position to maintain justifiably that a specific event *could* not have been produced by nature alone.

In considering this question, it should first be noted that no philosopher believes that we as human beings are in a position to state with absolute certainty what nature could or could not produce on its own. All acknowledge that the scientific enterprise is continually discovering new, often startling and unexpected, information about the causal relationships that obtain in our universe. And all freely admit that the annals of science record numerous instances in which supposed counterinstances to natural laws were later demonstrated to be consistent with such laws or revisions of them.

However, as some philosophers (such as Swinburne 1967 and Holland 1965) see it, some of our natural laws are so highly confirmed that any modification we might suggest to accommodate counterinstances would be clumsy and so *ad hoc* that it would upset the whole structure of science. For example, from their perspective, to attempt to modify our current laws relating to the properties of water to allow for the possibility that water could turn into wine naturally, or to attempt to modify our current laws relating to the properties of nonliving human tissue to allow for the possibility that a dead body could be resuscitated naturally, would make these laws of little practical value. Consequently, if we were in a position to maintain justifiably that a counterinstance to a law of this type had actually occurred, we would be required, for the sake of the scientific enterprise, to maintain that this event was permanently unexplainable by natural causes - that this event could never have been produced by nature on its own.

Critics (for instance, Basinger and Basinger 1986) consider this line of reasoning to contain a false dilemma. If faced with an acknowledged counterinstance to a natural law, even one that was very highly confirmed, we would not, they contend, be required at that moment either to modify the law to accommodate the occurrence or to affirm the adequacy of the law and declare the event permanently unexplainable by natural causes. Rather, since only naturally repeatable counterinstances falsify natural laws, the appropriate initial response to the occurrence of any seeming counterinstance to any law, no matter how highly confirmed, would be to acknowledge both the law and the counterinstance while further research was undertaken.

Moreover, these critics argue that such research could never make it most reasonable to conclude that something beyond the ability of nature to produce had actually occurred. If it were discovered that the seeming counterinstance was naturally repeatable - if it were found that the event in question could be produced with regularity under some set of purely natural conditions - a revision of the relevant laws would indeed be necessary. But then this event would no longer be naturally unexplainable. On the other hand, if natural repeatability could not be achieved, the appropriate response, they contend, would still not be to maintain that this occurrence was permanently unexplainable. Since nonrepeatable counterinstances do not present us with competing hypotheses to the relevant law(s), the appropriate response, rather, would be to label the counterinstance an anomaly while continuing to accept the functional adequacy of the law(s) in question.

Even if this line of reasoning is correct, however, nothing of significance follows for those who maintain only that a miracle is an event that would not have occurred at the exact time and in the exact manner it did if God had not somehow directly circumvented or modified the natural order in the specific case in question. Only those who believe that a miracle must be a violation of a natural law - who believe that a miracle must be an event that nature could not have produced - are affected.

5 Miracles as acts of God

Regardless of the perceived relationship between miracles and nature, however, questions concerning our ability (or inability) to identify events as direct acts of God remain important. For many philosophers, the most significant question of this sort continues to be whether there are imaginable conditions under which all rational individuals would be forced to acknowledge that God has directly intervened. And although most philosophers believe the answer to be no, some (for example, Larmer 1988) believe an affirmative response is required. They acknowledge that with respect to many states of affairs which believers do in fact maintain have been brought about by God - for example, many alleged cases of divine healings - it is possible for a rational person to grant that the event has occurred as reported and yet justifiably deny that it was the result of direct divine intervention. But let us assume that someone who has been dead for twenty-four hours is raised from the dead when divine intervention is requested. Or let us assume that the missing fingers of a leper instantaneously reappear following a prayer for healing. In such cases, they argue, there would be very strong evidence supporting supernatural causation and no evidence supporting purely natural causation. In fact, the evidence would be so strong that to continue to hold out indefinitely for a totally natural explanation in such contexts would be unjustified in that this would simply demonstrate an unreasonable a priori naturalistic bias.

In response, critics (for example, Basinger and Basinger 1986) do not deny that there might be conceivable cases which, if considered in isolation, would appear to make divine intervention a very plausible causal hypothesis. However, to acknowledge that God exists and has beneficially intervened in some specific case(s), they point out, is also to acknowledge that God’s existence is compatible with all we experience - for example, that it is compatible with the tremendous amount of horrific human pain and suffering that appears to fall disproportionately on the innocent and disadvantaged. And even if it is possible to claim justifiably that God’s existence is compatible with all we experience, it cannot be argued successfully that everyone must agree. Disbelief in God also remains a justifiable response (see Evil, problem of §6). Consequently, these critics conclude, the belief that there exists a solely natural cause for any specific occurrence always remains a justifiable option, regardless of the extent to which it may appear that divine intervention was involved.

For many philosophers, though, the crucial question is not whether there are imaginable conditions under which all rational individuals would be compelled to acknowledge divine intervention but rather whether there are conditions under which those who already believe in God would be justified in doing so. Even if it is true that the

occurrence of no single event (or set of events) can justifiably compel belief in divine intervention, it is also true (so philosophers such as Wainwright 1988 and Abraham 1985 contend) that the occurrence of no event (or set of events) - for instance, no amount of evil - can rule out justified belief in God's existence as a supernatural causal agent in our world. And given this fact, it is argued, as long as believers themselves possess good theistic reasons for assuming that God has directly intervened in a given case - for instance, because the occurrence appears clearly to fit an accepted pattern of divine action - they are justified in making this assumption.

It must be added, however, that even if this is correct, an important inverse relationship between miracles and evil remains. For instance, to respond to evil by claiming that God cannot both grant humans significant freedom and yet beneficially intervene on a consistent basis is, at the same time, to cite a reason why miracles should not be expected with frequency. And to respond to evil by claiming that 'God's ways are above our ways' places the believer in a less secure position to say when and where miraculous intervention has occurred.

mKhas grub dge legs dpal bzang po (1385-1438)

mKhas grub dge legs dpal bzang po (Kaydrup gelek belsangbo) was one of the early masters of the dGa'-ldan-pa (Gandenba) or dGe-lugs-pa (Gelukba) school of Tibetan Buddhism. His importance derives primarily from his close association with the founder of that school, Tsong kha pa (Dzongkaba, 1357-1419), whose religious and philosophical tradition he was instrumental in preserving and transmitting. A prolific writer, whose interests ranged across the entire spectrum of Buddhist doctrine, from the exoteric (Sūtra) to the esoteric (Tantra), his work is highly regarded for its ability to encapsulate lucidly entire fields of knowledge (for example, Tantra, the Mādhyamika doctrine of emptiness, and the pramāṇa *tradition of logic and epistemology).*

mKhas grub dge legs dpal bzang po (Kaydrup gelek belsangbo; often called mKhas grub rje) was born in Western Tibet in 1385. Like his younger brother, Ba so Chos kyi rgyal mtshan (Baso chogyi gyeltsen, 1402-73), another important figure in the early dGe-lugs-pa school, he became a novice monk at an early age and studied under some of the most distinguished masters of the Sa-skya-pa school, including the great Red mda' ba gZhon nu blo gros (Rendawa Shönnu lodrö, 1349-1412), one of Tsong kha pa's own teachers, from whom mKhas grub rje received full ordination at the age of twenty (see Tsong kha pa Blo bzang grags pa). As was the custom, he made the rounds of the great Tibetan monastic universities of his day, pitting his knowledge of the Buddhist doctrinal tradition against that of his peers and establishing a reputation as a great debater. Especially important in this regard was his encounter (at a mere sixteen years of age) with the renowned Bo dong Phyogs las rnam rgyal (Bodong choklay namgyel, 1375-1450), in debate with whom he is said to have defended, with great flair, the views of Sa skya Paṇḍita (Sagya paṇḍita, 1182-1251).

In 1407, on Red mda' ba's advice, mKhas grub rje went to central Tibet in search of Tsong kha pa (Dzongkaba). An instant rapport was established between the two when they met. In the dGe-lugs-pa tradition to this day, mKhas grub rje is known as the closest of Tsong kha pa's spiritual sons. From the time of his meeting with Tsong kha pa, mKhas grub rje began to apply himself earnestly to the study of the latter's teachings, receiving instruction as well from Tsong kha pa's more senior student and direct heir, rGyal tshab dar ma rin chen (Gyeltsap darma rinchen, 1364-1432). He succeeded rGyal tshab rje as the heir to the lineage of Tsong kha pa, becoming the third holder of the throne of dGa'-ldan monastery, a position that he held until his death in 1438. mKhas grub rje's philosophical and religious views are preserved in the eleven volumes of his collected works (*gSungs 'bum*).

Most of mKhas grub rje's philosophical and religious writings have yet to be analysed by Western scholars. From the work done to date, however, we know that, following Tsong kha pa, the following themes were central to his philosophical systematization of Buddhist doctrine: (1) that the public study of the great textual tradition of India, and not the private oral instruction lineages prevalent in Tibet, should form the basis for Buddhist study and practice; (2) the importance of ethics, as epitomized in the monastic way of life, as the basis for Buddhist practice; (3) the importance of self-generation, that is, the visualization of oneself in the form of a deity, as a defining characteristic of Buddhist Tantra; (4) the fact that the emptiness that is the object of meditation in both the Sūtra (that is, the Madhyamaka) and Tantra (for example, in the Kālacakra) traditions is identical; (5) that even though the analytical understanding of emptiness must be transformed, through the practice of meditation, into direct yogic experience, the object of both the analytical and yogic insights - the emptiness itself - is the same, so that emptiness as the object of analytical/conceptual thought is not a lower or corrupt form of emptiness (as maintained by some of Tsong kha pa's opponents) but is instead, like the object of the more sublime yogic consciousness, the full-blown reality of things, the ultimate truth that is the true mode of existence of persons and phenomena; (6) that the methods of logic and epistemology as systematized in the Prāmāṇika tradition of India are indispensable to the spiritual path, and, especially, to the initial understanding of emptiness; (7) that the highest expression of the Madhyamaka theory of emptiness, that of Candrakīrti's Čast;Prāsaōgika, is compatible with the overall thrust of the Indian logical/epistemological (*pramāṇa*) tradition, and, especially, that the principle of contradiction is valid even in the Madhyamaka system, so that the understanding of emptiness does not require a deviant logic which repudiates that principle; (8) that since conventional reality is the basis for the acquisition of the merit essential to spiritual progress, emptiness is not a repudiation of the existence of things, but only the negation of a specific false quality attributed to things by the ignorance innate in all sentient beings; and (9) that systems of meditation that repudiate analysis and conceptualization represent quietist/nihilist corruptions of the Buddha's teachings.

It is important to note that much of mKhas grub rje’s philosophical work is at least partially polemical in tone. This derives on the one hand from a personal predilection for a combative style of argumentation acquired and refined on the debating grounds of Tibet’s great monasteries. On the other hand, his polemical style is a direct outcome of the task he set himself, namely, that of clearly demarcating, systematizing and defending the doctrines of his master, Tsong kha pa.

Modal logic

Modal logic, narrowly conceived, is the study of principles of reasoning involving necessity and possibility. More broadly, it encompasses a number of structurally similar inferential systems. In this sense, deontic logic (which concerns obligation, permission and related notions) and epistemic logic (which concerns knowledge and related notions) are branches of modal logic. Still more broadly, modal logic is the study of the class of all possible formal systems of this nature.

It is customary to take the language of modal logic to be that obtained by adding one-place operators ' $\Box$*' for necessity and '* $\Diamond$ *' for possibility to the language of classical propositional or predicate logic. Necessity and possibility are interdefinable in the presence of negation:*

$\Box A \leftrightarrow \neg\Diamond\neg A$ and

$\Diamond A \leftrightarrow \neg\Box\neg A$

hold. A modal logic is a set of formulas of this language that contains these biconditionals and meets three additional conditions: it contains all instances of theorems of classical logic; it is closed under modus ponens *(that is, if it contains A and* $A \rightarrow B$ *it also contains B); and it is closed under substitution (that is, if it contains A then it contains any substitution instance of A; any result of uniformly substituting formulas for sentence letters in A). To obtain a logic that adequately characterizes metaphysical necessity and possibility requires certain additional axiom and rule schemas:*

$$\begin{array}{rl} K & \Box(A \rightarrow B) \rightarrow (\Box A \rightarrow \Box B) \\ T & \Box A \rightarrow A \\ 5 & \Diamond A \rightarrow \Box\Diamond A \\ Necessitation & A/\Box A. \end{array}$$

By adding these and one of the $\Box$*-* $\Diamond$ *biconditionals to a standard axiomatization of classical propositional logic one obtains an axiomatization of the most important modal logic, S5, so named because it is the logic generated by the fifth of the systems in Lewis and Langford's* Symbolic Logic *(1932). S5 can be characterized more directly by possible-worlds models. Each such model specifies a set of possible worlds and assigns truth-values to atomic sentences relative to these worlds. Truth-values of classical compounds at a world w depend in the usual way on truth-values of their components.* $\Box A$ *is true at w if A is true at all worlds of the model;* $\Diamond A$*, if A is true at some world of the model. S5 comprises the formulas true at all worlds in all such models. Many modal logics weaker than S5 can be characterized by models which specify, besides a set of possible worlds, a relation of 'accessibility' or relative possibility on this set.* $\Box A$ *is true at a world w if A is true at all worlds accessible from w, that is, at all worlds that would be possible if w were actual. Of the schemas listed above, only K is true in all these models, but each of the others is true when accessibility meets an appropriate constraint.*

The addition of modal operators to predicate logic poses additional conceptual and mathematical difficulties. On one conception a model for quantified modal logic specifies, besides a set of worlds, the set D_w *of individuals that exist in w, for each world w. For example,* $\exists x\Box A$ *is true at w if there is some element of* D_w *that satisfies A in every possible world. If A is satisfied only by existent individuals in any given world* $\exists x\Box A$ *thus implies that there are necessary individuals; individuals that exist in every accessible possible world. If A is satisfied by non-existents there can be models and assignments that satisfy A, but not* $\exists x A$*. Consequently, on this conception modal predicate logic is not an extension of its classical counterpart.*

The modern development of modal logic has been criticized on several grounds, and some philosophers have expressed scepticism about the intelligibility of the notion of necessity that it is supposed to describe.

1 History

Modal logic in the narrow sense was a topic of considerable interest to ancient and medieval philosophers. It occupied two chapters of Aristotle's *De Interpretatione*, and a substantial part of the *Prior Analytics*. Discussion of argument forms involving necessity and possibility that included, and sometimes transcended, commentary on

Aristotle's was standard fare in Hellenistic and medieval treatises on logic (see Logic, medieval). From our vantage point the ancient and medieval discussion can be interpreted as including distinctions among various kinds of possibility and necessity and investigations of the logical relations among them, as well as logical investigations of the interactions between modalities and negation, modalities and conditionals or consequence, and modalities and quantifier expressions. Aristotle determines in *De Interpretatione*, for example, that 'It may be' and 'It cannot be' are contradictories, as are 'It may not be' and 'It cannot not be' (see Logic, ancient). Furthermore, 'from the proposition ''It may be'' it follows that it is not impossible' and in one sense 'the proposition ''It may be'' follows from the proposition ''It is necessary that it should be'''. In another sense (which we might gloss as 'It is merely possible that'), 'It may be' is logically incompatible with 'It is necessary that it should be'.

Besides these purely modal principles, Aristotle and his commentators were concerned with arguments that we might think of as mixing time and modality. A notorious example is the fallacious 'sea battle' argument for determinism that he tries to debunk in *De Interpretatione* (see Aristotle §20). In addition to the admixture of temporal considerations, one should observe that the notion of necessity involved in these discussions is not likely to be the same as the one whose logical behaviour was summarized above. Aristotle himself catalogues four senses of the word 'necessary' in *Metaphysics* (V 5), and makes other distinctions elsewhere.

Although necessity and possibility have never ceased to play an important role in philosophical discourse, their logical properties were largely neglected in modern philosophy until the beginning of the twentieth century. The contemporary revival was sparked by C.I. Lewis' critique of Whitehead and Russell's *Principia Mathematica*. The logical system elaborated in *Principia* contained as theorems the formulas $p \supset (q \supset p)$ and $\sim p \supset (p \supset q)$, which Whitehead and Russell understood as asserting the apparently paradoxical propositions that if a sentence is true it is implied by any sentence and if a sentence is false it implies any sentence. Lewis maintained that these propositions, while unavoidable and unobjectionable with respect to Russell and Whitehead's understanding of implication, were false with respect to a more natural 'strict' sense of implication (see Relevance logic and entailment §§1-2).

Lewis embarked on a project of determining the appropriate axioms of strict implication with which to supplement this system. In *Principia* the 'material' implication $p \supset q$ is considered true unless *p* is true and *q* false. In Lewis' systems, the strict implication $p \Rightarrow q$ is considered true only if it is *impossible* that *p* is true and *q* false. Thus Lewis' strict implication can be defined from Russell and Whitehead's conjunction and negation signs and a new connective, '$\Diamond$', of possibility.

$$p \Rightarrow q = \sim\Diamond(p \mathbin{\&} \sim q)$$

Conversely, possibility can be defined from strict implication.

$$\Diamond p = \sim(p \Rightarrow \sim p)$$

Hence Lewis' project of finding the correct logical principles for his notion of strict implication is tantamount to that of finding the correct logical principles for possibility or, equivalently, those for necessity.

Lewis and Langford's *Symbolic Logic* (1932) describes five different axiom systems as candidates for the logic of strict implication. Much effort was expended in the first half of the century investigating these systems and variations of them. Even showing that all five are distinct (in the sense that they produce different classes of theorems) required considerable ingenuity. Fifteen years after the publication of *Symbolic Logic*, Carnap (1947) gave a non-axiomatic characterization of 'logical' necessity. $\ulcorner \text{Necessarily } A \urcorner$ is true, according to Carnap, if *A* is 'L-true', that is, if *A* is true in all state descriptions. (A 'state description' is a kind of canonical inventory of the primitive relations that hold and fail to hold of each sequence of individuals.) Thus Carnap can be seen as making precise the old idea that necessity is truth in all possible worlds. This idea is usually associated with Leibniz, but it is traced to Descartes by Curley (1984) and to Duns Scotus by Knuuttila (1982).

The logic determined by Carnap's interpretation turned out to be S5, the fifth of the Lewis and Langford systems. In the late 1950s and early 1960s, several authors proposed interpretations that refined and generalized Carnap's idea by introducing something like the accessibility relation described above (see Kanger 1957; Montague 1960; Hintikka 1963; Kripke 1963). 'Kripke models', which are essentially the models described above, are the neatest formulation of this idea. Kripke and a continuing line of successors have shown that a great variety of modal

systems can be characterized by models of this kind. This enormously simplified the kinds of investigations of axiomatic systems mentioned above and opened new lines of research.

Kripke models were particularly fruitful in the study of modal logic in the broader sense. It had long been noted that the pairs ‘it will always/sometimes be the case that’, ‘it is obligatory/permitted that’ and ‘it is known/consistent with knowledge that’ exhibit logical behaviour similar to that of ‘necessarily/possibly’. The success of Kripke’s treatment of necessity encouraged analogous treatments of these other notions.

GA (⌜It will always be the case that A⌝) is true at time *t* if *A* is true at all times after *t*.
FA (⌜It will sometimes be the case that A⌝) is true at *t* if *A* is true at some times after *t*.
OA (⌜It is obligatory that A⌝) is true at world *w* if *A* is true at all worlds at which the obligations of *w* are discharged.
PA (⌜It is permitted that A⌝) is true at *w* if *A* is true at some such worlds.
KA (⌜It is known that A⌝) is true at world *w* if *A* is true in all worlds consistent with what is known at *w*.

The resulting systems are labelled ‘tense logic’, ‘deontic logic’ and ‘epistemic logic’ to distinguish them from the original ‘alethic’ modal systems for necessity. In the last two areas this account probably takes the analogy with necessity too far, but it still serves as a useful point of departure (see Deontic logic; Epistemic logic).

Among other broadly modal systems that have received attention recently are the ‘dynamic logics’ or ‘logics of computation’ for reasoning about computer programs. Here worlds become computation states, which can be thought of as specifications of all the program variables at a particular time, and relative possibility becomes program accessibility, which holds between two states if a program can start in the first and terminate in the second. Such logics may be useful in verifying, without interminable testing, that a large program is ‘correct’, that is, that it does what it is supposed to do (see Dynamic logics).

The development of accessibility semantics led naturally to general questions about the classes of systems that can be characterized by various versions of it. Some of these are discussed below. Before the development of the accessibility interpretation, questions about the scope of axiomatic systems were often answered by devising suitable algebraic interpretations, and algebraic methods remain important tools for studying more general questions. Possible worlds semantics, however, seems less *ad hoc* than the algebraic methods. It is not clear whether they provide an analysis of necessity and possibility, or whether the notions that they incorporate, possible world and accessibility, are themselves to be analysed in terms of necessity and possibility. Either way, there is a close fit between the meanings of modal terms and their possible-worlds interpretations. The notion of possible world has proved useful in philosophical discussions on topics other than necessity and possibility: supervenience, causality, and the nature of propositions, properties and relations, to mention a few examples. The general utility of possible worlds has, in turn, inspired modal languages more expressive than the standard ‘box and diamond’ variety.

2 Propositional S5

As suggested above, S5 is the set of formulas provable from the axioms of classical propositional logic (PL) together with the axiom schemas *K*, *T*, *5* and $\Diamond A \leftrightarrow \neg\Box\neg A$ (henceforth $\mathrm{Df}\Diamond$) and the rules *modus ponens* (MP) and necessitation (Nec). It is important to understand that Nec states that $\Box A$ is a theorem if *A* is, and not that $\Box A$ is true if *A* is. Given *T* and the replacement of equivalents, the latter condition would make $\Box A$ and *A* freely interchangeable, rendering modal logic pointless.

To identify a modal system in this way with its theorems and to refer to such systems as modal logics is to follow standard, though misleading, practices. One would expect a ‘logic’ to indicate which conclusions follow logically from which premises, and perhaps the deductions by which they so follow. Furthermore, although S5 and other modal systems are intended to represent formal truths, that is, sentences true in virtue of form, it is not clear that they are intended to represent *logical* truths, that is, sentences true in virtue of logical form, for it is not clear that necessity is a logical constant (see Logical form; Logical constants). The first of these concerns can be somewhat reduced by stipulating that *A* follows from a set of formulas with respect to a logic *L* if, and only if, *L* contains a conditional whose antecedent is a conjunction of those formulas and whose consequent is *A*.

A model (for S5) is a pair (W, V) where *W* is a non-empty set (the possible worlds) and *V* is a function (the

valuation function) that assigns a truth-value (T or F) to each sentence letter and each possible world $w \in W$. If $M = (W, V)$ is a model and $w \in W$, the notion '*A* is true at *w* in *M*' (written $(M, w) \models A$) is defined inductively, the key clauses being:

$(M, w) \models \Box B$ if, for all $v \in W$, $(M, v) \models B$; and
$(M, w) \models \Diamond B$ if, for some $v \in W$ $(M, v) \models B$.

A formula is true in *M* if it is true at all possible worlds in *M*, and it is valid if it is true in all S5-models.

The 'soundness theorem' for S5 says that the semantics respects the logic in the sense that every formula in the logic is valid. The 'completeness theorem' states that every valid formula is in the logic. To say that S5 is both sound and complete with respect to the interpretation given is to say that validity and theoremhood coincide. Soundness is proved by an easy inductive argument appealing to the axiomatization: each axiom is observed to be valid and the two rules are shown to preserve validity. Completeness requires more ingenuity. A common approach is to adapt Henkin's proof of the completeness of classical logic. (For details see Lemmon (1966) or Chellas (1980).) One can get an idea of the value of an interpretation and completeness theorem by trying, with and without them, to demonstrate that $\Box p \rightarrow \Box\Box p$ is a theorem of S5.

In S5, all 'nesting' or 'iteration' of modality can be eliminated. For example, if a formula has the form $M_1 \ldots M_n A$ where each M_i is $\Box$, $\Diamond$ or negation, an equivalent formula can be obtained by deleting all the $\Box$'s and $\Diamond$'s except the innermost. Taking a modality to be a string of $\Box$'s, $\Diamond$'s and $\neg$'s, it follows that there are only six non-equivalent modalities in S5: the empty string, $\neg$, $\Box$, $\Diamond$, $\neg\Box$ and $\neg\Diamond$, corresponding to simple truth, falsity, necessity, possibility, non-necessity and impossibility.

One important schema of classical propositional logic that is not provable in S5 is extensionality:

(Ext) $(A \leftrightarrow A') \rightarrow (B \leftrightarrow B')$, where B' is the result of replacing an occurrence of the subformula *A* in *B* by A'.

For example, if *p* and *q* are both true at world *w* but only *q* is true at world *v*, then

$$(p \leftrightarrow q) \rightarrow (\Box p \leftrightarrow \Box q)$$

is false at *w*. By completeness it follows that

$$(p \leftrightarrow q) \rightarrow (\Box p \leftrightarrow \Box q)$$

is not a theorem of S5. Ext says that replacement of one subformula by another of the same truth-value will not affect the truth-value of the whole. Its failure is often viewed as characteristic of modal systems in general. Note, however, that provably equivalent formulas can be substituted for each other.

S5 is a relatively strong modal system. Its only extensions are the trivial logic, containing all instances of $\Box A \leftrightarrow A$ and, for every natural number *n*, the '*n*-possibility logic', containing all instances of

$$(\Diamond A_1 \wedge \ldots \wedge \Diamond A_{n+1}) \rightarrow \text{Dis},$$

where *Dis* is the disjunction of all formulas $\Diamond(A_i \wedge A_j)$ such that $i < j \leq n + 1$. (*n*-possibility logic is complete with respect to the class of all models with at most *n* possible worlds.)

The formulas of (propositional) S5 correspond to formulas of classical monadic predicate logic in one variable. For example, $\Diamond(p_1 \wedge \Box p_2)$ corresponds to $\exists x(P_1 x \wedge \forall x P_2 x)$. Since decision procedures for monadic predicate logic are known, this correspondence allows one to determine effectively whether a formula is in S5 by testing the corresponding monadic formula for validity. A more direct proof of decidability rests on the result that S5 has the 'finite model' property: every non-theorem is false in some model with finitely many worlds. To test whether *A* is in S5, one checks first whether *A* is provable in one step or falsifiable in a one-world model, then whether it is provable in two steps or falsifiable in a two-world model, and so on. Each step can be completed in finite time. By the finite model property, there is some step *n* at which the process yields the desired answer.

3 Philosophical questions about S5

The most important philosophical question about S5 is whether it captures the inferences and truths it was intended

to. This may depend, of course, on the kind of necessity that '$\Box$' is supposed to represent. On the usual view this is broadly logical or metaphysical necessity. Truths necessary in this sense include those true in virtue of logical form (the logical truths), those true in virtue of meaning (the analytic truths) and a more problematic category of those true in virtue of the basic nature of things. The last category has been said to contain truths of mathematics, the proposition that water is H_2O, and the proposition that Queen Elizabeth came from the egg and sperm that she did (see Essentialism). All these examples are controversial, but those who argue whether particular propositions are metaphysically necessary may nevertheless share a common conception of what it is to be metaphysically necessary. Furthermore, examples of propositions that lack metaphysical necessity seem uncontroversial: 'Napoleon invaded Russia', 'Asbestos is carcinogenic', 'Paris is the capital of France'.

The question of whether S5 (or any other system) is the right 'logic' for metaphysical necessity can be divided into two parts, corresponding to the two parts of the completeness theorem. Say that S5 is 'correct' if every theorem represents a formal truth about metaphysical necessity. Say that it is 'adequate' if every formal truth (with 'and', 'not', 'or' and 'if' as well as 'necessarily' and 'possibly') is represented by a theorem. Correctness and adequacy, then, are philosophical counterparts of soundness and completeness.

Correctness can be established by an argument similar to that for soundness: first show that the axioms represent formal truths and then that the rules transform formulas representing formal truths into formulas representing formal truths. Instances of axiom schema *T*, for example, clearly represent formal truths. ('If necessarily $87+25=112$ then $87+25=112$' is true in virtue of its form.) The difficult cases are axiom schema 5 and the rule Nec. For the former case we need to establish that sentences of the form ⌜If possibly *S* then necessarily possibly S⌝ are true in virtue of their form. One argument is as follows. To say possibly *S* is to say that ⌜$\mathrm{Not}\ S$⌝ does not follow logically or analytically from a description of the natures of things or from logical truths or analytic truths, that is, that *S* is logically and analytically consistent with the basic natures of things. But a proposition that something is consistent with logical laws, meanings and basic natures in this way is true or false in virtue of those logical laws, meanings and basic natures. So ⌜$\mathrm{Possibly}\ S$⌝, if true, is necessarily true. And since this argument does not appeal to *S*, the conditional is true in virtue of its form. An argument for the rule Nec might go as follows. Once it is established that all the axioms represent formal truths and that MP preserves formal truth, we know that everything proved without Nec represents a formal truth. Since formal truths are either logical or analytic, they are necessarily true. Since the argument that any of these sentences *S* is necessary relies only on the form of *S*, necessarily *S* is true in virtue of its form. This establishes that the first application of Nec results in formulas that represent formal truths. But if a sentence *S* proved with one application of Nec is shown to be a formal, and hence necessary, truth by an argument that appeals only to *S*'s form, then ⌜$\mathrm{Necessarily}\ S$⌝ must be true in virtue of its form. In this way, the argument can be extended to any subsequent application of Nec.

Adequacy might be established indirectly. Suppose that S5 were not adequate for metaphysical necessity. Then there would be some formal truth *S*, with 'necessarily', 'possibly', 'and' and so on, represented by a formula *A* that is not a theorem of S5. We should, then, be able to 'improve' the adequacy of S5 by adding *A* as an axiom. Furthermore, all the substitution instances of *A* will represent sentences with the form of *S*, which, if *S* is a formal truth, will also be formal truths. So we should be able to add all the substitution instances of *A* as well, obtaining an extension of S5. But, as was noted above, the extensions of S5 must contain either $\Box A \leftrightarrow A$ or, for some *n*, $(\Diamond A_1 \wedge \ldots \wedge \Diamond A_{n+1}) \rightarrow \mathrm{Dis}$. All these are incorrect for metaphysical necessity.

4 Quantified S5

Consider a language obtained by adding '$\Box$' and '$\Diamond$' and a special predicate *E* of existence to a version of predicate logic with predicates $P_1, P_2, \ldots,$ individual constants, $t_1, t_2, \ldots,$ and the identity sign, '$=$'. A model is a triple (W, D, V) where *W* is a non-empty set (the possible worlds), *D* is a function that assigns to each $w \in W$ a set D_w (the domain of *w*) and *V* is a function that assigns to each constant *t* a member of the union $\cup D$ of the sets D_w (the possible object 'denoted' by t_i) and to each world and *n*-place predicate an *n*-ary relation on $\cup D$. A definition of truth at a world is obtained from the previous one by replacing the base clause and adding clauses for '$\forall$', '$\exists$', '$=$' and *E*. The quantifier clauses state that, for example, $\forall x Px$ is true at *w* if, for every *d* in D_w, *Pt* is true at *w* when *t* denotes *d*, and that $\exists x Px$ is true at *w* if, for some *d* in D_w, *Pt* is true at *w* when *t* denotes *d*. $s=t$ is true at *w* if *s* and *t* denote the same possible objects. *Es* is true at *w* if $V(s) \in D_w$.

This interpretation reflects several choices. First, constants are ‘objectual’, that is, *V* assigns a possible object directly to each constant. $\Box Pcd$ is true at *w* if the possible objects $V(c)$ and $V(d)$ are related, at every world *w*, by $V(P, w)$. Thus $\Box Pcd$ expresses a *de re* necessity: it asserts that particular objects, independently of their descriptions, are necessarily related. This treatment of constants makes the schemas

$$(c = d) \rightarrow \Box(c = d) \qquad (\text{‘necessary identity’}) \text{ and}$$
$$\neg(c = d) \rightarrow \Box\neg(c = d) \qquad (\text{‘necessary difference’})$$

valid. Kripke has influentially argued that this is appropriate if *c* and *d* represent proper names of natural language, but generally inappropriate if they represent definite descriptions (see Proper names). The alternative to treating constants objectually is to allow their denotations to vary from world to world. An (individual) concept is a function from worlds to individuals. For example, the concept ‘first person to reach the South Pole’ might assign Amundsen to this world, Scott to the possible world in which Scott wins his race with Amundsen, and nothing to possible worlds in which the Pole is never (or always) occupied by people. We can regard a constant with a non-objectual interpretation as denoting a concept rather than an individual. On this ‘conceptual’ interpretation, necessary identity and necessary difference are not valid. Quantification may be treated conceptually as well: $\forall xA$ is declared true at *w* if every individual concept assigns to *w* an object to which *A* applies at *w*. In that case, quantified necessary identity and difference formulas,

$$\forall x \forall y(x = y \rightarrow \Box x = y) \text{ and}$$
$$\forall x \forall y(\neg(x = y) \rightarrow \Box\neg(x = y)),$$

lose their validity as well. The quantification described above, by contrast, is objectual.

Second, quantification is ‘actualist’. The truth of $\forall xPx$ at *w* requires only that the objects in D_w have the appropriate property. It follows that the Barcan formula

$$\forall x\Box Px \rightarrow \Box\forall xPx$$

and its converse

$$\Box\forall xPx \rightarrow \forall x\Box Px$$

are both invalid. Suppose, for example, that for some world *w*, *P* is a predicate that holds everywhere of just the objects that exist in *w*, and that D_u contains something not in D_w. Then at *w*, ‘Everything is necessarily *P*’ is true while ‘Necessarily, everything is *P*’ is false. Conversely, suppose that, at every world *w*, *P* holds of just the objects that exist at *w*, and that D_v contains something not in D_u. Then at *v* ‘Necessarily everything is *P*’ is true, while ‘Everything is necessarily *P*’ is false. More generally, $\forall x\Box\forall y\Box A$, $\Box\forall x\forall y\Box A$, $\Box\forall x\Box\forall yA$, and $\Box\forall x\Box\forall y\Box A$ are logically distinct.

If quantification is ‘possibilist’, that is, if $\forall xA$ means that *A* is true of all objects in $\cup D$, then these formulas are all equivalent and the Barcan formula and its converse are valid. The distinction between actualist and possibilist quantification is significant only because the models defined above have domains that vary from world to world. If one stipulates ‘constant domains’, that is, that $D_u = D_v$ for all worlds *u* and *v*, then the possible objects are just the actual ones, and the distinction collapses. Barcan and its converse are again valid.

Third, predicates can be truthfully applied to constants denoting non-actual objects. Since quantification is actualist, this implies that the classical theorems $Pc \rightarrow \exists xPx$ and $\forall xPx \rightarrow Pc$ are not valid. These principles can be retained by insisting that the application of predicates to constants denoting non-actuals is always false (defining models so that $V(P_i, w)$ is a relation on D_w). But to do so would be to adopt a kind of atomism according to which the properties and relations expressed by atomic formulas with free variables had a special status. Furthermore, although it would save the particular classical theorems above, some of their substitution instances, such as $\neg Ex \rightarrow \exists x\neg Ex$, would still fail. Another alternative is to stipulate that formulas in which predicates are applied to constants denoting non-existents lack truth-value. If validity is taken as ‘false in no model’, both the formulas and their instances are saved. On the other hand, that approach would seem to make $\Box Ec$ valid (if necessity is ‘nowhere false’) or to make $\Box(Fc \vee \neg Fc)$ invalid (if necessity is ‘everywhere true’).

Finally, domains are permitted to be empty. This implies that

$\Diamond\exists x(Fx \vee \neg Fx), \Box\exists x(Fx \vee \neg Fx)$ and $\exists x(Fx \vee \neg Fx)$

are all invalid. If one regards the first as expressing a formal truth, one can require that some world have non-empty domain; if the second, that all worlds do. If one regards the third as expressing a formal truth one can require that each model specify - in addition to the possible worlds, domains, and valuation - a particular possible world (the actual) that has a non-empty domain. Truth in a model is then redefined as truth at the actual world of the model.

5 Weaker systems

A Kripke model is a triple (W, R, V), where *W* and *V* are as in §2, and *R* (accessibility) is a binary relation on *W*. Truth at a world is defined as before except for the '$\Box$' and '$\Diamond$' clauses:

$$(M, w) \models \Box A \text{ if, for all } v \in W \text{ such that } wRv, \quad (M, v) \models A$$
$$(M, w) \models \Diamond A \text{ if, for some } v \in W \text{ such that } wRv, \quad (M, v) \models A$$

Truth in a model and validity are defined as before. The formulas valid in this sense comprise the logic K. K can be axiomatized by the schemas PL, *K* and $\mathrm{Df}\Diamond$ and the rules MP and Nec. Since it lacks the schema $\Box A \rightarrow A$, K is not adequate for necessity under any construal. It occupies an important position in modal logic in the broader sense, however, because many well-known modal systems are simple extensions of it. The systems in the leftmost column of the table, for example, are obtained by adding the schemas in the middle column to PL, *K* and $\mathrm{Df}\Diamond$ and the rules MP and Nec.

System	Characteristic axioms	Conditions on *R*
D	D: $\Box A \rightarrow \Diamond A$	seriality: $\forall x \exists y Rxy$
T	*T*	reflexivity: $\forall x Rxx$
S4	*T 4*: $\Box A \rightarrow \Box\Box A$	reflexivity transitivity: $\forall x \forall y \forall z(Rxy \mathbin{\&} Ryz \rightarrow Rxz)$
S4.3	*T, 4* H: $\Diamond A \mathbin{\&} \Diamond B \rightarrow \Diamond(A \wedge \Diamond B) \vee \Diamond(\Diamond A \wedge B) \vee \Diamond(A \wedge B)$	reflexivity, transitivity connectedness: $\forall x \forall y(Rxy \vee Ryx)$
GL	W: $\Box(\Box A \rightarrow A) \rightarrow \Box A$	transitivity no infinite chains: $Rx_1x_2 \mathbin{\&} Rx_2x_3 \mathbin{\&} \ldots \rightarrow \exists i(x_i = x_{i+1})$

The schema *D* (see the table) is formally true when '$\Box$' and '$\Diamond$' are read 'it is obligatory that' and 'it is permitted that', and the system D is known as the standard deontic logic. T was one of the earliest modal logics to be characterized precisely (see Feys 1937, 1938) and it seems to be the weakest logic in which '$\Box$' can plausibly be regarded as representing a reading of 'it is necessary that'. If, as some have suggested, the remaining S5 axioms are not correct for physical necessity, T would be a plausible candidate for the logic of that notion. S4 was the fourth of the Lewis systems. Gödel (1933) gave it a characterization like the one above and showed it to be intertranslatable with intuitionistic propositional logic. S4.3 (so named, in part, because it is intermediate in strength between S4 and S5) is correct and adequate for a reading of '$\Box$' as 'it is and always will be the case that' if time is assumed to be linear (see Tense and temporal logic). If sentence letters represent statements about numbers and '$\Box$' is interpreted as 'provable in arithmetic' then the system GL contains exactly the formulas that are themselves provable in arithmetic (where a statement about provability is 'provable' if its Gödel number is the number of a theorem of arithmetic - see Gödel's theorems). By adding all instances of $\Box A \rightarrow A$ to the theorems of GL (without allowing any new applications of the rule Nec) one obtains the system GLS, which may be regarded as the logic of arithmetic provability. Whereas GL comprises the arithmetically provable formulas about provability, GLS comprises the truths about provability (see Provability logic).

Each of these logics can also be characterized semantically, just as we have done with K. A ‘D-model’ is a Kripke model whose accessibility relation is ‘serial’, that is, every world is related to some world or other, and models appropriate for each of the other systems can be similarly defined by the conditions in the table. In each case, soundness and completeness results like those for S5 sketched above can be given.

Not all broadly ‘modal’ systems can plausibly be interpreted by Kripke models. Suppose $\Box A$ is read ‘usually *A*’. There is no relation on times such that ‘usually *A*’ is true now if *A* is true at all related times. Rather, the truth of ‘usually *A*’ depends on the number, and perhaps the distribution, of all the times at which *A* is true. This suggests a more general kind of modal semantics, one formulation of which is the ‘neighbourhood semantics’. A ‘neighbourhood model’ is a triple (W, R, V), where *W* and *V* are as before, and *R* is a relation between worlds and sets of worlds (the ‘neighbourhoods’ of those worlds, although there is no requirement that the neighbourhood of a world contain the world itself, or even that it be non-empty). The definition of truth at a world is as before except that $\Box A$ is true at *w* just in case *w* is related to the ‘truth-set’ of *A*, that is, the set of worlds at which *A* is true; and $\Diamond A$ is true at *w* if *w* is unrelated to the ‘falsity-set’ of *A*.

The modal system determined by the set of all such models is the system E, axiomatized by the schemas PL and $\mathrm{Df}\Diamond$ and rules MP and ‘equivalents’ (RE): ‘If $A \leftrightarrow B$ is provable, so is $\Box A \leftrightarrow \Box B$’. Like K, E provides a convenient base from which a variety of systems of interest can be constructed, rather than a characterization of the formal truths for some particular reading of ‘ $\Box$’. This idea can be carried even further. Operator logic (OL) is the system in the language with ‘ $\Box$’ that is axiomatized just by PL (see Kuhn 1981). The modal operators of S5, K, E and OL can be regarded as being successively more schematic and having successively less content, the theorems of OL being the modal sentences that are true in virtue of their logical form, and the stronger modal systems being theories of operators based on that logic.

6 General results

Much of the contemporary study of modal logic is directed, not towards investigating any particular one of the systems described above in more detail, but towards a general understanding of classes of such systems. The modal logics, as defined above, form a lattice structure. A Kripke model $M = (W, R, V)$ can be viewed as the addition of a valuation *V* to the ‘Kripke frame’ (W, R). *M* is then said to be ‘based on’ (W, R). Similarly, the neighbourhood model (W, N, V) is based on the neighbourhood frame (W, N). A formula is valid in a frame if it is true in all models based on the frame, and it is valid in a class of frames if it is valid in all frames of the class. A ‘frame for *L*’ is a frame in which all the theorems of *L* are valid. The set of formulas valid in a class of frames is a logic, the logic determined by that class. A logic is sound for a class of frames if every formula in the logic is valid in the class; it is sufficient for the class if every formula valid in the class is a member of the logic; it is complete (for the class) if it is sound and sufficient.

The logic determined by a class of frames is, by definition, complete for that class. It might also be complete for other classes. K, for example, is determined by (and therefore complete for) the irreflexive Kripke frames as well as all Kripke frames. Fine (1974) and Thomason (1974) independently showed that there are finitely axiomatizable extensions of K that are not determined by any class of Kripke frames. Such logics are incomplete: formulas true in every frame that verifies the axioms are unprovable. It is now known that the incompleteness phenomenon is widespread. For every extension *L* of the logic T there are uncountably many incomplete logics whose frames are exactly the frames for *L*. (This result holds for both Kripke frames and neighbourhood frames; see Benton 1985.) The incomplete logics that have been exhibited in the literature are generally complex and *ad hoc*, but one simple example is obtained from GL by replacing the first conditional of the schema *W* by a biconditional. In the other direction, results of Bull (1966) and Fine (1971) imply that every extension of S4.3 that admits the necessitation rule is complete and decidable.

Much work has also been done on the correspondences between modal and classical formulas. The schema *T* corresponds to the classical formula $\forall x Rxx$ in the sense that the frames for the former are just the first-order models for the latter. Most modal schemas that have arisen naturally in philosophical discussion correspond similarly to first-order formulas. The schemas in the second column of the table, for example, correspond to formulas in the third column. The McKinsey schema, $\Box\Diamond A \rightarrow \Diamond\Box A$, on the other hand, corresponds to no first-order formula (see van Benthem 1975; Goldblatt 1975), and no modal schema corresponds to irreflexivity:

$\forall x \neg Rxx$. (The latter fact follows from the remark above that K itself is complete for the irreflexive frames.)

The general study of modal logic encompasses a variety of other topics, including: model theory (transformations of frames and models may preserve truth-values of classes of formulas); boundary investigations (some logics have properties that all their extensions lack); expressive power (some classes of modal connectives can be defined from a few representatives); and connections with non-modal logics (such as that between S4 and intuitionistic logic). The completeness and correspondence investigations discussed above, however, have formed the core of contemporary investigations.

Modal logic, philosophical issues in

In reasoning we often use words such as 'necessarily', 'possibly', 'can', 'could', 'must' and so on. For example, if we know that an argument is valid, then we know that it is necessarily *true that if the premises are true, then the conclusion is true. Modal logic starts with such modal words and the inferences involving them. The exploration of these inferences has led to a variety of formal systems, and their interpretation is now most often built on the concept of a possible world.*

Standard non-modal logic shows us how to understand logical words such as 'not', 'and' and 'or', which are truth-functional. The modal concepts are not truth-functional: knowing that p is true (and what 'necessarily' means) does not automatically enable one to determine whether 'Necessarily p' is true. ('It is necessary that all people have been people' is true, but 'It is necessary that no English monarch was born in Montana' is false, even though the simpler constituents - 'All people have been people' and 'No English monarch was born in Montana'- are both true.)

The study of modal logic has helped in the understanding of many other contexts for sentences that are not truth-functional, such as 'ought' ('It ought to be the case that p') and 'believes' ('Alice believes that p'); and also in the consideration of the interaction between quantifiers and non-truth-functional contexts. In fact, much work in modern semantics has benefited from the extension of modal semantics introduced by Richard Montague in beginning the development of a systematic semantics for natural language.

The framework of possible worlds developed for modal logic has been fruitful in the analysis of many concepts. For example, by introducing the concept of relative possibility, Kripke showed how to model a variety of modal systems: a proposition is necessarily true at a possible world w if and only if it is true at every world that is possible relative to w. To achieve a better analysis of statements of ability, Mark Brown adapted the framework by modelling actions with sets of possible outcomes. John has the ability to hit the bull's-eye reliably if there is some action of John's such that every possible outcome of that action includes John's hitting the bull's-eye.

Modal logic and its semantics also raise many puzzles. What makes a modal claim true? How do we tell what is possible and what is necessary? Are there any possible things that do not exist (and what could that mean anyway)? Does the use of modal logic involve a commitment to essentialism? How can an individual exist in many different possible worlds?

1 What makes a modal claim true?

Alice ate vegetable soup today. What makes that true? Alice's activities and their relationship to vegetable soup. Alice *could have* eaten cream of tomato soup. What makes that true? This is less clear. No activity of Alice's seems to make this statement about possibilities true.

If we ask what makes something possible, the context of the question sometimes sets a standard: it was possible for Alice to have eaten cream of tomato soup because it was on the menu, there was plenty of it available, there was nothing barring her from ordering it and nothing standing in the way of the waiter's bringing it to her. Yet it seems that there is a more absolute sense of possibility, according to which it was at least logically possible for Alice to have eaten cream of rutabaga soup (even if no one had ever made such a thing), because no logical or conceptual barrier prevents its existence or her eating it.

In contrast, Alice could not eat cream of tomato soup without eating it, and she could not have vegetable soup that involved no vegetables at any stage of its preparation. For logical or conceptual reasons, these are not activities open to Alice. Not every description picks out something that is possible.

Once we get a view of this broader notion of possibility, it seems that possibility can get a negative characterization. A description of an event or state of affairs describes something possible if no logical or conceptual consideration rules out what it describes. It is possible if it is not impossible; and the impossible is whatever is ruled out by logical or conceptual considerations. If a proposition is necessary, then its negation is impossible. The proposition

If Alice eats tomato soup, then Alice eats tomato soup

is necessary; and so a negation of that, a proposition equivalent to

Alice eats tomato soup without eating tomato soup,

is impossible. It is necessary that

All vegetable soup involves vegetables in its preparation;

so it is impossible that

Something is vegetable soup and does not involve vegetables in its preparation.

Understanding what is impossible will follow upon an understanding of what is necessary.

All of this suggests that we can understand what makes something possible if we can get a general understanding of what makes something a necessary truth. An event or state of affairs *p* is not possible if and only if *p* is impossible; *p* is impossible if and only if the negation of *p*, $\sim p$, is necessary. Ordinarily the box symbol is used before a sentence to stand for necessity (‘ $\Box p$’ stands for ‘It is necessary that *p*’) and the diamond is used to stand for possibility (‘ $\Diamond p$’ stands for ‘It is possible that *p*’), and we have just taken note of these related equivalences:

$\Diamond p$ iff $\sim\Box\sim p$.
$\sim\Diamond p$ iff $\Box\sim p$.

Because of these logical relationships between possibility and necessity, we can understand what makes something possible by developing an understanding of what makes something necessary. A state of affairs is possible if and only if its negation is not necessary. So what makes something a necessary truth? Our examples so far have consisted of logical and conceptual truths, but it seems that the category of necessary truths is broader. My pet cat could not exist without being an animal; it is necessary that if she exists, then she is an animal. I could not have existed if a certain sperm and ovum had never existed; it is necessary that if I exist, then those cells existed. No right hand can precisely fill the space taken up by any left hand; it is necessary that if a space *S* is filled by a left hand, then *S* cannot be precisely filled by any right hand. Logic and definitions do not seem to suffice as the source of the necessity of these truths.

In exploring logical relationships, logicians have introduced the concept of a possible world. This has been of enormous benefit in understanding logical relationships among modal claims. A statement is a necessary truth if and only if it is true at every possible world; a statement is possibly true if and only if it is true at at least one possible world. Thus our symbols can be connected with a systematic semantics for modal language in which possible worlds are reference points:

Any sentence of the form ‘ $\Box p$’ is true iff *p* is true at every possible world.
Any sentence of the form ‘ $\Diamond p$’ is true iff *p* is true at at least one possible world.

Kripke’s elaboration of this, employing the notion of relative possibility, has been very important in exploring a range of modal systems that give a range of different results concerning the logical relationships among modal sentences (see Kripke, S.A.; Modal logic). With further elaboration, introducing a ‘closeness’ relation, this framework has been extended (see Lewis 1973, Stalnaker 1968) to provide a better semantics for counterfactuals: roughly, a counterfactual ‘If it were the case that *p*, then it would be the case that *q*’ is true at *w* if and only if *q* is true at all of the closest worlds to *w* in which *p* is true.

Such systematizations seem to give us an account of the necessity and possibility of propositions that can help us to see more clearly what is and what is not possible. This account, however, is not an ultimate answer to the question of what makes something possible, because there is no independent account of what a possible world is. We are left with the question of what makes it the case that Alice’s eating rutabaga soup is included in some possible worlds, whereas my cat’s being a plant is not. At a possible world, every necessary truth must be true, every state of affairs which obtains must be possible, and the possible world must meet some maximality condition (for example, that every proposition or its negation must be true at that world) - but then judging what is included in a possible world takes us back to the question of judging what is possible. So we have a circle of concepts. The

exploration of such a circle of concepts can be very enlightening concerning their logical relationships, and it can help us to make more consistent judgments about the application of the concepts, but it cannot give an independent answer to the question of what makes a modal statement true (see Possible worlds; Semantics, possible worlds).

Thus we are led to a root philosophical problem about modality, the problem of giving a general account of what makes modal claims and related claims true - or, which amounts to the same problem, the problem of saying in general what makes a set of propositions true of a possible world (or what makes a set of states of affairs constitute a possible world). Any answer that is non-modal seems inadequate, and any answer that is modal merely enlarges the circle. Perhaps the kind of understanding that we get by enlarging the circle and exploring the relationships among modal concepts is the best we can hope for (see Blackburn 1993).

2 The merely possible

Even when we work within the circle of modal concepts, attempting to get a coherent, systematic semantics for modal claims, we come upon many puzzles. Understanding the relationship between the actual and the possible is at the root of much of the difficulty.

It seems clear that there could have been more carrier pigeons. If people had not shot so many of them, they would be flying now, perhaps in flocks so large that they would darken the skies. In saying this - in using the word ‘they’ to refer to some carrier pigeons that *would be* flying now - I seem to be referring to carrier pigeons that do not exist. Are there carrier pigeons that do not exist, that is, some nonexistent, merely possible carrier pigeons? We should hope not. Yet in a systematic treatment of modality, it is difficult to avoid the problem of requiring the existence of merely possible objects, and various strategies have been employed to deal with this problem. (Not everyone regards a commitment to nonexistent objects as a problem; see Meinong, A.)

One strategy is to note a distinction between existence and actuality. Some things - possibilia - exist without being actual, and the merely possible carrier pigeons are among them. In fact, it might be said that if possible worlds exist without being actual, why should we regard it as a new problem to accept the existence of the things that make up those worlds, such as possible carrier pigeons? If the possible worlds exist, it seems that the things in them should exist as well. The use of modal language commits us to both possible worlds and possibilia, according to this view.

The view that there are some merely possible objects, just as there are merely possible worlds, seems grounded in a puzzle, however, and we can separate that view from the thesis that other possible worlds exist. A distinction between existence and actuality makes sense for possible worlds, on most conceptions, because a possible world is really an abstract representation; a way things might be, rather than a way in which they are. (The conception for which David Lewis argues is an important exception to this; see Lewis 1986.) Thus we can say that there are worlds very much like this one except that Quine becomes a full-time geographer and never becomes a philosopher. There are such ways for things to be, but they are not actualized: things are not that way. This distinction between existing and being actualized holds among worlds as it does for stories or dreams, because a world is a way things might be; a maximal state of affairs or a maximally consistent set of propositions. This distinction does not carry over to individuals such as Quine and carrier pigeons. If non-actual carrier pigeons are carrier pigeons, then they are not the sort of thing that can exist without being actualized. This is the puzzle of possibilia, because we cannot see how any carrier pigeon can exist without being actual (in the way that a story can exist without being actual), and the idea that possible worlds and possible objects are on an existential par seems unacceptable. Possibilia cannot simply ride in on the coat tails of possible worlds.

One way out of this is to interpret the semantics as being about something more abstract than individuals - concepts or individual essences (see Plantinga 1974, for example). Instead of using the ordinary concept of satisfaction in the semantics, we can use a concept ‘satisfactionČast;’, saying that an individual essence *e* satisfies* ‘*x* is a geographer’ at a world *w* if and only if *e* is an essence of something that would be a geographer if that world, *w*, were actual. These individual essences can then be things that exist even when they are not actualized and that are actualized by the same individual at every world at which they are actualized. The individual essences of many carrier pigeons exist without being actualized. That is why it is true that other carrier pigeons could have existed.

On this view, individual essences rather than individuals are components of propositions. This allows the

propositions to exist even when the individuals do not exist. This conflicts with David Kaplan's view that a typical singular proposition is contingently existent, existing only in those possible worlds in which the individual that it is about exists (see Kaplan 1989; Demonstratives and indexicals §2). But it need not conflict with his more central views: that singular propositions do not contain concepts that can be used to pick out the individual the proposition is about; and that the propositional component is determined by the individual rather than the other way around. This would only mean that possible worlds in which an individual does not exist provide no resources for singling out that individual's essence. Nothing in this approach conflicts with that.

The approach in terms of essences leaves puzzles, too. What are these things? How many of them are there? These questions are not easy to answer, and so we are left with some discomfort in understanding modal claims no matter how we try to deal with the problem of possibilia.

3 Quantification, modality and essentialism

Many of those who have considered the concept of necessity have regarded it as a logical concept, applying to sentences in virtue of their form. An idea like one of the following would be typical.

A sentence of the form ‘ $\Box p$’ is true iff *p* is a logical truth.
A sentence of the form ‘ $\Box p$’ is true iff *p* is analytic.

W.V. Quine has expressed grave misgivings about this at two levels. First, he questions the intelligibility of the notion of analyticity, and at times seems even to question the concept of logical truth. Thus he will reject any notion of necessity construed in this way. Quine's misgivings about logical truth and analyticity are explored elsewhere (see Analyticity).

Quine (1961, 1966) has a further objection to the intermingling of quantifiers and modalities. Even if one grants a concept of analyticity or logical truth to serve as the basis for the concept of necessity, there are two problems for quantified modal logic: the problem of quantifying into modal contexts; and the related problem of intersubstituting coreferential names.

We can see the problem of quantifying in more easily if we consider first the problem of quantifying into truth-functional contexts. This is a real problem, because we ordinarily give an account of truth-functional connectives in terms of the truth-values of the constituents. Thus ‘ $Fa \,\&\, Ga$’ is true if and only if ‘*Fa*’ is true and ‘*Ga*’ is true. However, if we quantify, writing ‘ $(\exists x)(Fx \,\&\, Gx)$’, then ‘Čamp;’ no longer connects two sentences that have a definite truth-value. Some new interpretation for ‘Čamp;’ must be found, so that we can understand how the semantic value of the unit ‘ $Fx \,\&\, Gx$’ is determined.

Tarski (1933) found a systematic way to do this. Even though ‘*Fx*’ has no truth-value, it has a truth-value *relative to an assignment of an individual i to* ‘*x*’. ‘ $Fx \,\&\, Gx$’ is true relative to an assignment if and only if ‘*Fx*’ is true relative to that assignment and ‘*Gx*’ is true relative to that assignment. We can also say that an assignment or an individual satisfies the open sentence ‘ $Fx \,\&\, Gx$’ if and only if it satisfies ‘*Fx*’ and satisfies ‘*Gx*’. This solves the problem of quantifying into truth-functional contexts (see Tarski's definition of truth).

To interpret ‘ $\exists x \Box Fx$’ we need to know when an individual *i* satisfies ‘ $\Box Fx$’. It is not so immediately evident how to account for this, especially if you think that the necessity of ‘*Fa*’ comes from features of ‘*Fa*’ (for example, an analytic association of ‘*a*’ with ‘*Fx*’) rather than from features of the individual *i* that ‘*a*’ denotes. An individual can be singled out by many different conditions, and perhaps some of those are analytically associated with ‘*Fx*’ though others are not. For example, the condition ‘ $x = 3^3$’ has ‘ $x > 7$’ as a necessary consequence (that is, it is a necessary truth that whatever satisfies one satisfies the other); but ‘*x* numbers the planets’ does not have this necessary consequence. The condition ‘ $x > 7$’ is necessarily connected with some ways of specifying nine but not with others. We can ask whether nine is necessarily greater than seven, but Quine finds no grounds for answering this question one way rather than another, because he believes that all necessity must be grounded in analytic consequence relationships and he finds no basis for favouring one specification of nine over the other. By this standard, either answer to the question of whether nine is necessarily greater than seven seems equally justified. Beginning with an account of necessity in terms of analyticity or logical truth should lead one to Quine's suspicions about quantification into this context.

The attempt to explain satisfaction of a modal condition in terms of analytic consequence seems doomed. But how else? Saying directly that some properties are necessary and others are not repels Quine. Quine sees such distinctions as an objectionable essentialism (see Essentialism), and accordingly he dismisses quantified modal logic.

Kripke provides an alternative account of what it is for an individual to satisfy ‘ $\Box Fx$’. The account, in terms of possible worlds, has puzzled Quine; and puzzlement about existence of an individual in different possible worlds is closely related to Quine’s puzzlement about essentialism. For existence in multiple possible worlds to have significance, it seems that there must be something that makes it possible for an individual to exist with some sets of properties and not others - some are essential and some are not. We must distinguish between properties that an individual has: for example, my cat satisfies ‘*x* is an animal’ and also ‘*x* has eaten chicken livers’, but she has the first property (being a cat) essentially and the second (having eaten chicken livers) only contingently. Kripke provides at least the formal framework for an account (1963), and in later work (1972) does much to defend the substantive metaphysics that goes with it.

Terence Parsons (1969) has pointed out that we can make at least one kind of distinction between essential and non-essential properties in a way that even Quine should not object to. Properties expressed by sentences of the form ‘If *Fx*, then *Fx*’ will be essential to everything. Such essential properties seem unproblematic. We encounter problematic essentialism only if we find two individuals that differ in their essential properties. This point is limited in its scope, however. Within any fixed model verifying the assumption that all individuals have the same essential properties, any sentence with quantifying in is true in all of the same worlds as some sentence that lacks quantifying in. The resources that troubled Quine - quantification into modal contexts - seem to serve no expressive purpose (see McKay 1975 and Fine 1978b).

4 Counterparts

Although Barney is eating a sandwich for lunch, he could have had a salad instead. Most modal theorists take that claim to involve the existence of a certain non-actual but possible situation: the possibility that Barney eats a salad for lunch.

David Lewis (1968) thinks that no such possible situation exists. Barney could have eaten a salad, but that really means that there is a possible world very much like this one in which the person most like Barney eats a salad. A non-actual world will never include Barney; it may, however, include a counterpart of Barney, an individual that is more like him than is any other in that world. The fact that one of his counterparts eats a salad makes it true that Barney could eat a salad, according to Lewis.

This approach has seemed unintuitive and ill-motivated to many (Plantinga (1974) and (Kripke 1972), for example). When considering what is possible for Barney, it seems natural to suppose that we are considering possibilities that involve Barney rather than someone else. In addition, it seems that in another possible world Barney could have been very different from the way he is while someone else was more like our actual Barney. As arguments against counterpart theory, however, such intuitive considerations are inconclusive. They might be answered by denials (citing a conflict of intuitions) or, for the last objection, by clarifications of the theory that elaborate the relevant similarity notion.

Formal considerations are also significant, however. The identity relation is transitive, but there is no reason to think that the counterpart relation is transitive, and this will produce different valid formulas. In the modal systems S4 and S5 (see Modal logic), for example, the following is ordinarily valid:

$$\forall x(\Diamond\Diamond Fx \rightarrow \Diamond Fx).$$

But as long as the counterpart relation is not transitive, we could not expect that to be valid, even in S5. (An individual *i* might have a counterpart that has a counterpart that satisfies ‘*Fx*’ even though no counterpart of *i* satisfies ‘*Fx*’.) Whether this difference would be an advantage or a drawback would need further consideration.

One technical feature is directly related to some of the intuitive considerations against counterpart theory. Lewis allows that an individual in one world might have two counterparts within a single world. If that is the case, then some laws involving identity will fail. Ordinarily, the principle of necessary identity is valid:

$\Box\forall x\forall y(x = y \rightarrow \Box x = y)$.

And there seems to be a good argument for this, based on two other fundamental principles, the necessity of self-identity and Leibniz's Law (see Identity):

$$\Box\forall x\Box x = x$$
$$\forall x\forall y(x = y \rightarrow (\phi x \leftrightarrow \phi y))$$

One substitution instance of Leibniz's Law is this:

$$\forall x\forall y(x = y \rightarrow (\Box x = x \leftrightarrow \Box x = y)).$$

Given the assumption of the necessity of self-identity, the principle of necessary identity then follows. To defend counterpart theory, one must locate a fault with the necessity of self-identity or with this application of Leibniz's Law, or one must add features to the counterpart theory that will validate the principle of necessary identity (see Forbes 1985).

5 The logic of ability

Having surveyed some of the difficulties in interpreting modal logic, we now return to an illustration of the use of the possible worlds framework to shed light on inferences that are important for philosophy.

Although 'might' and 'can' are often thought of as possibility operators, they are clearly different. 'John might hit the target' and 'John can [is able to] hit the target' are very different, and Mark Brown's semantics for a logic of ability extends the possible worlds resources to make it clear what the difference is (1988).

Suppose that John is throwing darts, but does not reliably hit the target. Is John *able* to hit the target? He might hit it, but he does not have an ability that enables him to hit it reliably. In ordinary discussion, 'John is able to hit the target' is perhaps ambiguous. It could represent 'He might hit it', but is more likely to mean 'He has the ability to hit it reliably'. This suggests that there are two possibility operators, and these are distinguishable in Brown's system.

We can also give a more formal motivation for such a system. When we consider the context 'He has the ability to…reliably', we find that it does not obey the following law $\mathrm{K}\Diamond$ of the most fundamental normal modal system K:

$$\Diamond(p \vee q) \rightarrow (\Diamond p \vee \Diamond q).$$

If John has the ability to hit the target reliably, then he is able to bring it about that he hits either the right half or the left half. It need not be true that he has the ability to hit the right half reliably, and it need not be true that he has the ability to hit the left half reliably. So $\mathrm{K}\Diamond$ does not seem true, if '$\Diamond$' is to represent an ability operator.

Also, in almost all standard modal systems (all that include T), we have this principle: $p \rightarrow \Diamond p$. But suppose that John will, by luck, hit the target. It does not follow that he has the ability to do that reliably. So $\mathrm{T}\Diamond$ is not true, if '$\Diamond$' is to represent an ability operator.

Brown introduces a family of new modal operators that we can add to the standard ones. We will use these symbols: ⟐, ◈, ⊡ and ⊟ The semantics is based on a binary relation *S*, relating worlds in *W* to sets of worlds (that is, $S \subseteq (W \times \wp(W))$). We can define the new modal operators as follows (where we use '*K*' as a variable for sets of possible worlds):

⟐*p* is true at *w* iff $\exists K$ such that wSK and $\forall w'$ such that $w' \in K$, *p* is true at w'. (Informally: John is able to bring it about that *p* reliably. John can perform some action such that *p* is sure to be true if that action is performed.)
◈*p* is true at *w* iff $\exists K$ such that wSK and $\exists w'$ such that $w' \in K$, *p* is true at w'. (John might bring it about that *p*. Some action that John can perform allows for the possibility of *p*.)
⊡*p* is true at *w* iff $\forall K$ such that wSK, $\exists w'$ such that $w' \in K$, *p* is true at w'. (No matter what John does, *p* might be true.)
⊟*p* is true at *w* iff $\forall K$ such that wSK, $\forall w'$ such that $w' \in K$, *p* is true at w'. (No matter what John does, *p* will

be true.)

Given this understanding of these operators, it is natural to make at least the following assumptions about the relation *S*, validating the formulas $⟐p \rightarrow ◈p$ and $p \rightarrow ◈p$:

$\forall w \forall K$ such that wSK, $K \neq \emptyset$. (Validates D ⟐: $⟐p \rightarrow ◈p$)

(Nothing John can do annihilates all possibilities. Everything John can do has some possible outcomes.)

$\forall w \exists K$ such that wSK and $w \in K$. (Validates T ◈: $p \rightarrow ◈p$)

(The actual world is a possible outcome of at least one of John's actions.)

Focus first on ⟐, the modal operator representing ability. If we think of an action as being represented by a set of possible outcomes, then we can consider each set *K* of possible worlds such that wSK to correspond to the outcomes of some action that the agent under consideration might take. Each such set *K* would be a set of possible worlds that might be actual if the agent performed some particular action. So if the agent can hit the dartboard, but has no control over where, then a set of possible worlds that vary in where the agent hits the dartboard would be a set *K* such that wSK, and it could correspond to the action of throwing a dart. To say that $⟐A$ is to say that there is some action (that is, some set *K* of outcomes; that is, some set *K* such that wSK) that guarantees *A* (that is, *A* is true throughout *K*). To say that the agent can hit the dartboard is to say that there is some such action (that is, some set *K* such that wSK, and throughout *K* the agent hits the dartboard).

The word 'could' is associated with possibility and ability. Three of our new modal operators involve possibility, and we can give an example that is three ways ambiguous:

He could win the lottery.

This could mean that he bought a ticket, and so nothing he can do would guarantee to make him a non-winner, that is, $⊠A$. This could mean that he can buy a ticket, and then he might win, that is, $◈A$. Or this could mean that he has special powers such that if he exercised them he would win, that is, $⟐A$. (The King could win the lottery (if he wanted to), but he hates to interfere in the peasants' fun.)

Thus we have a resource for disambiguation and for the exploration of logical relationships that are central to some philosophical work in ethics and metaphysics. Even though we have seen how many puzzles arise in the acceptance of the possible worlds framework, we should not lose sight of the many reasons we have to value it.

Modal operators

Modal logic is principally concerned with the alethic modalities of necessity and possibility, although this branch of logic is applied to a wide range of linguistic and conceptual phenomena, including natural language semantics, proof theory, theoretical computer science and the formal characterization of knowledge and belief. This wide range of application stems from the basic form of modal assertions, such as 'it is necessarily the case that ϕ*', where an entire statement* ϕ *is embedded within a context possessing rich logical structure.*

When constructing a formal representation of these embedding contexts, there are several choices concerning their specific symbolic form. The most standard approach symbolizes modal contexts as operators, which combine directly with formulas of the object language to yield new formulas. The primary alternative to this approach is to treat modal contexts as predicates, which attach not to formulas directly, but to names of formulas, and thereby attribute a metalinguistic property to a syntactic object. A variation on the operator approach, which assumes the interpretive framework of possible worlds semantics, is to treat modal contexts as quantifications over possible worlds. Finally, a variation on the predicate approach is to analyse modal contexts as predicates of propositions rather than as predicates of syntactic objects.

1 Monadic connectives

On the most standard approach, the modal operators '$\Box$' for necessity and '$\Diamond$' for possibility are introduced as new logical constants (although only one need be taken as primitive). These modal operators are syncategorematic expressions, since they are not assigned an explicit reference, rather their semantic import is carried in a recursive clause of the formal definition of truth. In terms of the syntactic formation rules, the modal operators behave as monadic connectives, structurally comparable to negation in classical logic. The modal assertion 'it is necessarily the case that ϕ' will have the symbolic form '$\Box\phi$', where the necessity connective 'operates' on the formula ϕ to yield the new formula '$\Box\phi$'. However, unlike the negation connective, the modal operators are not truth functional: it is not possible to determine the truth-value of a modal statement simply on the basis of the truth-value of the formula it embeds. In this sense, introduction of the modal operators constitutes a significant departure from the pure extensionality of classical logic, and this has led to criticism of their legitimacy, most notably from W.V. Quine.

Quine has argued that non-extensional contexts are logically permissible only if construed as 'referentially opaque', that is, the constituent symbols within these contexts are treated as occurring non-referentially. Quotation is a paradigmatic case of such a context since, for example, in the true statement '''John walks'' is a short sentence', the occurrence of the string 'John' does not refer to anyone (see Use/mention distinction and quotation). Quine (1953) argues that since modal contexts are non-extensional, they are properly viewed as quotational, wherein the embedded sentence ϕ is mentioned rather than used (this theme will be continued in §3; see Propositional attitudes §2). However, treatment of modal contexts as operators suggests that the logical structure of the embedded formula is semantically relevant, even though it occurs within a non-extensional context. Indeed, since '$\Box$' operates at the same linguistic level as the formula ϕ, it follows that the semantic value of ϕ should directly contribute to the compositional value of '$\Box\phi$'. Thus the '$\Box$' operator must utilize information not contained in the extension of the embedded expression.

2 Sorted quantifiers

According to possible worlds semantics for modal operators, introduced by Saul Kripke (1959), the non-extensional value of modal statements is determined by appeal to the extension of the embedded expression in alternative possible worlds (see Semantics, possible worlds). The sentence '$\Box\phi$' is evaluated as true at a given world just in case ϕ is true in all worlds possible relative to the given world, while the sentence '$\Diamond\phi$' is true just in case there is at least one possible world in which ϕ is true. So in this standard semantic framework, the truth definition for modal statements is specified in the metalanguage by quantifying over the set of possible worlds; the truth of an assertion of necessity is expressed in terms of a universal quantification, while an assertion of possibility is evaluated as an existential quantification. Somewhat more formally, a Kripke model M comes equipped with a set W of worlds (or points or indices) and a binary relation R on W such that a world $w' \in W$ is possible relative to a world $w \in W$ just in case wRw'. In the simplest case, where R is universal (that is, every

world in *W* is possible relative to itself and every other), reference to *R* can be dropped. Then '$\Box\phi$' is true in *w* just in case ϕ is true in all worlds $w' \in W$, and '$\Diamond\phi$' is true in *w* just in case there is at least one $w' \in W$ in which ϕ is true.

It is therefore possible to recast the logical form of modal statements as quantifiers rather than operators, where the structure of the truth definition is explicitly manifested in the structure of the object-language formula. In the general case, this will require the use of many-sorted quantificational logic, where the domain of discourse is divided into distinct subdomains, and typographically different variables are used to quantify over these respective subsets. In the modal case, the set W of possible worlds will form one such subdomain, and a distinct type of intensional variable will range over this set. Thus where the extension of an expression ψ varies according to the index of evaluation, this same 'intensional' effect can be mirrored by adding a variable to yield the expression $\psi(i)$, where i ranges over possible worlds. The interpretation function will assign to ψ a value which gives the standard type of extension when applied to worlds as arguments. To translate operator modality into the quantifier formulation, a straightforward mapping is defined where $(\psi)^* = \psi(i)$ for nonlogical constants ψ, where logical form is preserved for the extensional connectives and where $(\Box\phi)^* = \forall i(\phi)^*$ and $(\Diamond\phi)^* = \exists i(\phi)^*$. In this manner, the necessity operator is explicitly recast as a universal quantifier, and possibility is represented as an existential quantifier. The quantifier approach is perhaps most attractive as an alternative to intensional type theory (see Montague, R.M.), where the different sorts of variables correspond to distinct logical types.

3 Predicates of expressions

While the quantifier interpretation is a natural variation on the use of operators (given the framework of possible worlds semantics), the predicate approach to modality constitutes a more divergent analysis. Under this development, modal contexts are symbolized by a monadic predicate, say *N*, which is categorematic and receives a normal first-order extension (that is, a set of objects). But admissible extensions of *N* must satisfy the constraints imposed by its intended meaning as a modal device, and in this sense *N* is comparable to the binary predicate symbol 'Čequals;' normally used to designate the identity relation.

On the predicate approach to modality, syntactic expressions are themselves named by singular terms, and the necessity predicate *N* attaches to such terms to yield new atomic formulas. Quotation is often adopted as a convenient method for constructing terms that name expressions. Thus if $\ulcorner\phi\urcorner$ is the official quotation term denoting the object-language formula ϕ, then the assertion that ϕ is necessary will have the form $N(\ulcorner\phi\urcorner)$. In this manner, modal formulas are viewed as attributing a metalinguistic property to a linguistic expression treated as an object of discourse. The two most natural properties to attribute in this context are that the object-language formula is valid with respect to some class of models, or that it is provable in some formal system. On this latter reading, the predicate approach is quite suitable for applications to proof theory (see Gödel's theorems §6) and for applications to the symbol-processing accounts of epistemic contexts common in artificial intelligence.

On the predicate analysis, the named formula is mentioned rather than used, and this is amenable to the Carnap-Quine position that the logic of modalities should be expressed in an extensional metalanguage (see Carnap 1937), and that the attempt to express modality in an intensional object language rests on a confusion between use and mention. It is also compatible with Quine's view (see §1) that modal contexts are referentially opaque. The fact that the modal predicate attaches to a term denoting a formula indicates that there are no free variables inside a modal context, and this would prohibit the articulation of quantified modal logic. Therefore, Quine has argued that the only legitimate development of 'intensional' logic is comprised by that fragment which can be rendered in terms of the extensional clarity of a metalinguistic predicate.

However, Montague (1963) has subsequently demonstrated that for any language endowed with the 'self-referential' capacities of elementary number theory, the addition of even very weak modal assumptions leads to inconsistency under the predicate approach. In systems that extend the theory *Q* of Robinson arithmetic, Gödel's diagonal lemma establishes that for any open formula $\beta(x)$ with one free variable, there exists a closed formula θ such that $\vdash \theta \leftrightarrow \beta([\theta])$, where $[\theta]$ is the Gödel numeral code for θ. If necessity is formalized as a predicate $N(x)$ within such a system, then the diagonal lemma establishes that there will be a sentence μ such that $\vdash \mu \leftrightarrow \neg N([\mu])$, where μ 'says of itself' that it is not necessary. μ is the modal analogue of the celebrated Gödel sentence that asserts its own unprovability, and of the liar sentence that underpins Tarski's theorem on the undefinability of truth (see Semantic paradoxes and theories of truth). And in a manner analogous to the

Gödel-Tarski results, μ can be used to deduce a contradiction, given fairly minimal principles governing the logic of *N*.

In light of these negative results, the predicate view of modality must be approached with some care. A crucial point is that not all the formulas in which *N* occurs will correspond to statements that can be articulated using the resources of the operator. In particular, there is no operator counterpart to the 'self-referential' sentence μ, since the '$\Box$' connective must apply to formulas rather than to their names. And if radically new formulas such as μ are allowed to instantiate the relevant modal schemata, then new axioms are added to the modal system, and this in turn yields an unwanted increase in deductive power. Thus it is possible to avoid inconsistency by inverting the Quinean perspective and defining the predicate system so that it precisely mirrors the expressive-deductive power of the operator.

4 Predicates of propositions

In addition to treating them as predicates of syntactic objects, it is also possible to formalize modal contexts as predicates of semantic objects. In systems of higher-order intensional logic such as Montague's system IL, semantic value is divided along Fregean lines into both an extensional and an intensional component (see Sense and reference). Montague's scheme utilizes Carnap's insight that the intensional component of semantic value can be modelled as a function from possible worlds to extensions. The intension of a sentence is a proposition, while its extension is a truth-value, and hence a proposition is modelled as a (characteristic function of a) set of possible worlds, namely that set of worlds in which the sentence is true. The object language is equipped with an intensional operator 'ˆ' which, when attached to an expression, yields a term that denotes the intension of the expression. So the term $\hat{\phi}$ denotes the proposition expressed by ϕ, which is the set of possible worlds in which ϕ is true. Necessity can then be rendered as a higher-order predicate *Nec*, which applies to sets of worlds and is meant to assert that the set in question is identical to the set of all worlds in the model. In this framework, the statement that ϕ is necessary will then have the form $Nec(\hat{\phi})$, which asserts that the set of worlds constituting the intension of ϕ is identical to the set of all worlds in the model, and this is equivalent to the standard operator interpretation that ϕ is true in all possible worlds.

Model theory

Model theory studies the relations between sentences of a formal language and the interpretations (or 'structures') which make these sentences true or false. It offers precise definitions of truth, logical truth and consequence, meanings and modalities. These definitions and their consequences have revolutionized the teaching of elementary logic.

Model theory also forms a branch of mathematics concerned with the ways in which mathematical structures can be classified. This technical work has led to philosophically interesting results in at least two areas: it has thrown light on the nature of the set-theoretic universe, and in nonstandard analysis it has suggested new forms of argument (where we prove something different from what we intended, but then use a general model-theoretic argument to change the result into what we wanted).

The word 'model' has many other uses. For example, model theory is not about scientific theories as models of the world. It is also a controversial question - not considered here - how model theory is connected with the 'mental models' which appear in the psychology of reasoning.

1 Basic ideas

In 1954 Alfred Tarski announced that a new branch of metamathematics had come into being. He called it 'model theory'; it studied 'mutual relations between sentences of formalized theories and mathematical [structures] in which these sentences hold'. Model theory quickly became an active area of research on the boundary between logic and other branches of mathematics (see §5 below). The name 'model theory' is sometimes applied more broadly, particularly by philosophers, to include any inquiry which uses formal languages, structures and a truth definition. For example, a model-theoretic approach to English semantics is one which treats English as a formal language and attaches meanings to English phrases in terms of possible worlds, regarding these worlds as mathematical structures.

When Tarski spoke of a 'sentence of a formalized theory', he meant what logicians have also called a 'sentence schema', that is, a string of meaningful words and meaningless symbols (sometimes called schematic variables), which becomes a meaningful sentence when the symbols are given meanings. For example, the string

(1) Everything which is a P is a Q

is a sentence schema. If we interpret 'P' as meaning 'cow' and 'Q' as meaning 'quadruped', then the schema comes to mean the same as the sentence 'Every cow is a quadruped'. In model theory we always assume that the word 'everything' needs interpretation too; the interpretation will say what set of things counts as everything, and any set may be allowed. For example, if we take 'everything' to range over the set of objects in China, then the original string comes to mean 'Every object in China which is a cow is a quadruped'.

A 'mathematical structure' is a way of interpreting the symbols in a schema. It consists of a set of objects which is the range of quantifier words such as 'everything' and 'there exists'; and a family of sets, relations, functions and so on which express the meanings of the schematic variables. The set of objects is called the 'domain' or 'universe' of the structure, and its members are called the 'elements' of the structure. For example, the structure which gives our interpretation of (1) has the set of objects in China for its domain; it attaches the set of cows in China to the symbol 'P' and the set of quadrupeds in China to the symbol 'Q'. (More formally, we can regard a structure M as an ordered pair $\langle \mathrm{dom}(M), Y \rangle$ where dom(*M*) is the domain of *M* and *Y* is a function which takes each interpreted symbol *s* to its interpretation $Y(s)$, also written s^M. Many mathematical objects can also be thought of as structures in this sense; thus a group *G* is a pair $\langle X, Y \rangle$ where *X* is the set of elements of *G* and *Y* is a function taking the group product symbol '$\cdot$' to the group multiplication '$\cdot^G$'.)

In our schema (1), the meaningful expressions are those written in English. Model theorists often use logical symbols for the meaningful words. For example, 'and' is often written 'Čamp;' or '$\wedge$'; for 'it is not true that' one writes '$\sim$' or '$\neg$'; one writes '(x)' or '$\forall x$' to mean 'for every element *x*'. When this is done, a sentence schema is the same thing as a sentence of formal logic with uninterpreted non-logical symbols (see Predicate calculus).

2 Truth and satisfaction

The central device of model theory is the truth relation, written ‘ $\models$’. (Pronunciations vary, but ‘double turnstile’ is safe, using ‘turnstile’ for ‘ $\vdash$’.) Suppose ϕ is a sentence schema and *M* is a structure which interprets ϕ. Interpreted, ϕ says something which is either true or false. If it is true, we say that ϕ is true in *M*, or that *M* is a model of ϕ; in symbols, $M \models \phi$. Tarski showed how one can give a precise mathematical definition of the relation ‘ $\models$’. His definition is correct in the sense that it agrees with our intuitive notions about when an interpretation *M* makes a formula ϕ into a true sentence. (See Tarski’s definition of truth for the context of Tarski’s definition. See also Semantics, game-theoretic for an interesting variant.)

In defining ‘ $\models$’, Tarski assumed that each structure *M* is a set-theoretic object and that the schemas ϕ are sentences of a conventional formal logic. Also *M* must interpret every non-logical symbol in ϕ. It is usual to ensure this by stating Tarski’s definition relative to a set *S* of non-logical symbols; we assume that *M* interprets just these symbols, and that ϕ uses no non-logical symbols besides those in *S*. This set *S* is then called the ‘signature’ (or similarity type) of *M* and ϕ.

In fact Tarski defined a slightly more complicated relation, namely satisfaction. Suppose *M* is a structure, $a_1, \ldots, a_n$ are elements of *M* and $\phi(x_1, \ldots, x_n)$ is a formula with free variables $x_1, \ldots, x_n$. We write $M \models \phi[a_1, \ldots, a_n]$ (pronounced ‘ a_1 to a_n satisfy ϕ in *M*’) to mean that when *M* is used to interpret the symbols of ϕ apart from the free variables, and x_i is read as the name of the element a_i for $1 \leq i \leq n$, then ϕ becomes a true sentence. The truth relation is the special case where $n = 0$. (The set of all *n*-tuples $(a_1, \ldots, a_n)$ such that $M \models \phi[a_1, \ldots, a_n]$ holds is called the relation (or set) defined in *M* by ϕ.)

Tarski’s definition of satisfaction has several clauses, depending on the form of the formula ϕ. For example, if ϕ is of the form $\psi \wedge \chi$ then $M \models \phi[a_1, \ldots, a_n]$ holds if and only if $M \models \psi[a_1, \ldots a_n]$ and $M \models \chi[a_1, \ldots, a_n]$ both hold. If ϕ is of the form $\forall x_2 \psi(x_1, x_2)$, then $M \models \phi[a_1]$ holds if and only if for every element *b* of *M*, $M \models \psi[a_1, b]$ holds. These and similar clauses allow us to break ϕ down into its smallest component formulas, known as atomic formulas. For atomic formulas, Tarski’s definition refers directly to the interpretations of symbols given by the structure *M*.

By applying Tarski’s definition, we can reduce the statement that $M \models \phi[a_1, \ldots, a_n]$ to a purely set-theoretic statement. To illustrate this, let $\phi(x)$ be the first-order formula ‘ $\forall y(y = c \wedge Py \rightarrow y = x)$’, and let *M* be a structure with a set P^M to interpret the symbol ‘*P*’ and an element c^M to interpret the constant *c*. Suppose *b* is an element of *M*. Then according to Tarski’s definition of satisfaction (with a very small simplification),

(2) $M \models \phi[b]$

holds if and only if

(3) $\{c^M\} \cap P^M \subseteq \{b\}$.

(Intuitively, every member of the set P^M which is equal to c^M is equal to *b*. The schema ϕ defines in *M* the set $\{c^M\}$ if c^M is in P^M, and the set of all elements of *M* otherwise.)

3 Classes defined by axioms

Model theory grew out of a development in mathematics. Around the turn of the twentieth century it was becoming common to define classes of structures in terms of the axioms which are true in them; such classes are said to be axiomatically defined. The classes of groups, rings and Boolean algebras are three examples (see Boolean algebra). Certain questions arise naturally in this context. Let us note three. First, what can we tell about an axiomatically defined class by looking at the syntactic form of its axioms? Second, given an axiomatically defined class, when is one of the symbols redundant in the sense that its meaning in any structure in the class is determined by the meanings of the other symbols? Third, given a set of axioms *T*, one of which is ϕ, when is ϕ redundant in the sense that the class axiomatically defined by *T* would not be altered if we left out ϕ? These are all typical questions of model theory.

By a theory we mean a set of sentences of a formal language. We say that a structure *M* is a model of the theory *T* if *M* is a model of every sentence in *T*. So the class of all models of *T* is the axiomatically defined class whose set

of axioms is *T*. First-order model theory, which is by far the largest part of the subject, studies the case where *T* is a set of first-order sentences. Many interesting mathematical classes of structures - including groups, rings and Boolean algebras - are defined by first-order axioms.

Here are two sample theorems of first-order model theory, which illustrate the first and second questions above. We shall turn to the third question in the next section.

Two structures are said to be ‘elementarily equivalent’ if they are models of exactly the same first-order sentences. Our first theorem states that if *M* is a structure with infinitely many elements and λ is an infinite cardinal, then we can cut down *M* (if it has more than λ elements) or add new elements (if it has fewer) so as to form a structure *N* which is elementarily equivalent to *M* and has exactly λ elements. This theorem is known as the downward Löwenheim-Skolem theorem (when elements are removed) or the upward Löwenheim-Skolem theorem (when elements are added). The upward and downward theorems together are equivalent to the axiom of choice, which is an indication that in general it is impossible to give an explicit description of *N*. The upward theorem follows from the compactness theorem of §4.

If *T* is a first-order theory, and a symbol *R* of the signature of *T* is redundant in the sense described at the start of this section, then we say that *R* is implicitly definable relative to *T*. Our second theorem states that if *R* is implicitly definable relative to *T*, then it is explicitly definable in the sense that there is some first-order sentence which is true in all models of *T* and which says, ‘*R* means such-and-such’. (See Beth’s theorem and Craig’s theorem for further details.) In practice this theorem is generally used backwards: we are given that *R* is not explicitly definable relative to *T*, and we use the theorem to find two models of *T* which agree in the interpretations of all symbols except *R*.

4 Semantic and syntactic consequence in first-order logic

The question of redundant axioms goes back several hundred years. Already in the thirteenth century Persian geometers were trying to show Euclid’s parallel postulate to be redundant in his axioms for geometry. In fact it is not, and proofs of this fact by Beltrami and others in the late nineteenth century gave a boost to the development of model theory. Beltrami introduced the word ‘interpretation’ in 1868.

Some notation will help. If *T* is a theory and ϕ a sentence, we write

(4) $T \models \phi$

to mean that every model of *T* is also a model of ϕ. (4) is sometimes read ‘ ϕ is a semantic consequence of *T*’. (This double use of ‘ $\models$’ is unfortunate, but the usage has become firmly entrenched. In (4) there is a theory to the left of ‘ $\models$’, not a structure as in (2).) So ϕ is redundant in the theory consisting of *T* and ϕ, if and only if $T \models \phi$.

The central theorem here is Gödel’s completeness theorem, proved in his doctoral dissertation of 1929 and published in 1930. It states that if *T* and ϕ are first-order, then (4) holds if and only if ϕ is deducible from *T* in a standard proof calculus for first-order logic. We write $T \vdash \phi$ when this condition holds; so Gödel’s theorem says that the structural relation ‘ $\models$’ (in the sense of (4)) is equivalent to the purely syntactic relation ‘ $\vdash$’. Like all later logicians, Gödel proved his theorem by assuming that ϕ is not deducible from *T* and constructing a model of *T* in which ϕ is false. Later logicians have usually built the model out of the expressions of the first-order language; Gödel, perhaps influenced by Hilbert’s constructions of counterexamples in geometry, used numbers as the elements of the model and showed that appropriate relations could be found to interpret the symbols of the language. (See Gödel’s theorems. Gödel proved his theorem for one particular proof calculus and a countable signature, but both these restrictions are unnecessary.)

Of the many applications of Gödel’s completeness theorem, two are worth noting here. First, when *T* is the empty theory in (4), we leave it out and write simply ‘ $\models \phi$’; and likewise with ‘ $\vdash$’. Compare the forms of the following two statements.

(5) $\vdash \phi$, that is, there is a proof of ϕ
(6) $\models \phi$, that is, there is not a model of $\neg\phi$.

By Gödel’s theorem, (5) and (6) are equivalent, both saying that ϕ is a theorem (or valid sentence) of first-order

logic. The difference between the forms of (5) and (6) is very convenient. If ϕ is a theorem, according to (5) we can show it by giving a proof of ϕ. If ϕ is not a theorem, then by (6) we can show it by giving a structure in which ϕ is not true. Either way, we know what we have to produce in order to establish the fact. (A strengthening of the completeness theorem, proved independently by Hasenjäger and Kleene in 1952, allows us to do better. If ϕ is a first-order sentence but not a theorem, then there is a model of $\neg\phi$ which consists of the natural numbers together with some arithmetically definable sets, relations and functions. So in the second case we can specify the model by giving some arithmetical formulas.)

Now that we know Gödel's theorem, we can try to prove a first-order sentence ϕ by showing that its negation $\neg\phi$ has no model. This idea leads quickly to tableau proofs (see Natural deduction, tableau and sequent systems §4). Of course the tableau method itself is a purely syntactic calculus. But it can be motivated very directly in terms of the model-theoretic relation (4); with a good class of students one can explain the principle and leave it as a homework exercise to work out the rules.

Second, suppose *T* is a first-order theory and every finite subset of *T* has a model. Then there is no finite subset T' of *T* such that every model of T' is a model of the contradictory statement '$\neg\forall x\ x = x$' (since no structure is a model of this statement). So by Gödel's theorem, *T* has no finite subset from which we can formally prove '$\neg\forall x\ x = x$'. But then we cannot prove '$\neg\forall x\ x = x$' from *T* at all, since any formal proof would use only a finite part of *T*. Hence by Gödel's theorem again, it is not true that every model of *T* is a model of the contradiction; in other words, *T* has a model. By this roundabout route we have deduced the 'compactness theorem': if every finite subset of a first-order theory has a model, then the whole theory has a model. This is the single most important theorem of model theory. All the applications in the next section use it.

5 First-order model theory: four applications

This section relates some of the mathematical successes of first-order model theory. It can be skipped without breaking continuity.

First, suppose *T* is a first-order theory, and for every natural number *n* there is a model M_n of *T* in which there are at least *n* elements which satisfy the formula *Px*. For each *n* we can write a first-order sentence which says, 'There are at least *n* elements *x* such that *Px*'; let *U* be the set of these sentences for all *n*. Our assumption about *T* implies that if we take just finitely many sentences from *U*, then there is some model of *T* in which all these sentences are true. Then the compactness theorem tells us that there is a model of *T* in which all the sentences are true, so that infinitely many elements satisfy *Px*. This argument has many applications. It shows, for example, that if *T* has arbitrarily large finite models then *T* has an infinite model. It also shows that there is a structure *N* which is elementarily equivalent to the field *R* of real numbers (and in fact contains it), but which has infinitesimal elements; these are elements greater than 0 but less than 1, $\frac{1}{2}$, $\frac{1}{3}$ and so on. Since *N* contains infinitesimals, we can do calculus in *N* in the way that Leibniz intended, calculating $\mathrm{d}y/\mathrm{d}x$ as a ratio of two infinitesimal numbers d*y* and d*x* (this is a slight oversimplification). Suppose that we can use infinitesimals to prove that a certain first-order sentence ϕ is true in *N*. Then ϕ must be true in *R* too, since *R* and *N* are elementarily equivalent. This ingenious way of doing calculus has sprouted into a new branch of mathematics (see Analysis, nonstandard).

In 1982 Shelah gave a very different application of model theory. Confining himself to structures of countable signature, he looked at elementary equivalence classes, that is, classes that consist of a structure and every other structure elementarily equivalent to it. Two structures are said to be isomorphic if one is an exact copy of the other. (Formally, *M* is isomorphic to *N* if there is a bijection from the domain of *M* to that of *N*, which takes the interpretation s^M of each symbol *s* of the signature to the interpretation s^N.) Shelah proved that a dichotomy holds: each elementary equivalence class is either very good or very bad. 'Very good' means that we can classify all the structures in the class, up to isomorphism, by means of a few numerical invariants (such as dimension in the case of vector spaces). 'Very bad' means that we can construct two structures in the class which are not isomorphic but are extremely hard to distinguish from each other. Shelah sees this work as a step towards bringing the more chaotic areas of mathematics under control.

In 1992 Hrushovski and Zil'ber proved a theorem which says that algebraically closed fields can be recognized through certain model-theoretic properties of their Zariski topologies. Hrushovski then used this result to prove an open case of the geometric Mordell-Lang conjecture (an important conjecture in diophantine geometry). Zil'ber

had long been convinced that there must be some kind of characterization of algebraically closed fields in terms of their model-theoretic properties, partly because these fields are such fundamental objects in mathematics. It was also partly because Macintyre had already shown that if *M* is an infinite field, then *M* is algebraically closed if and only if the set *T* of all first-order sentences true in *M* is λ-categorical for every uncountable cardinal λ - that is, that any two models of *T* with exactly λ elements must be isomorphic. (A theory is said to be categorical if all its models are isomorphic. By the upward Löwenheim-Skolem theorem, if a first-order theory has a model with infinitely many elements, then it cannot be categorical, though it may be λ-categorical for some cardinal λ.)

Finally, one achievement of the twentieth century has been to base all mathematics on axiomatic set theory. A theorem is reckoned to be proved if we know in principle how to write it as a formal deduction from the axioms of ZF (Zermelo-Fraenkel set theory). Unfortunately ZF seems to leave unanswered many natural questions about sets and infinite cardinals. Since the 1960s, set theorists have studied these questions by examining models of the ZF axioms. For example, in 1963 Paul Cohen showed that the axiom of choice is not deducible from the other axioms of ZF, by constructing models of these other axioms in which the axiom of choice is false. Model theorists have devised several techniques for constructing interesting models of a given theory, and two of these techniques have led to other advances in set theory. Ultraproducts, which are good for constructing 'fat' models in which there are as many types of element as possible, are an essential tool for studying the colossal (but possibly non-existent) cardinals that set theorists call large cardinals. The technique of indiscernibles, which constructs 'thin' models with as few types of element as possible, is used to show the enormous differences between Gödel's constructible universe and a universe of sets which contains very large cardinals. (See Set theory.)

6 Limitations of first-order model theory in mathematics

First-order logic has a delicate balance of expressiveness: it can say things about a fixed number of elements at a time, but it is very bad at expressing statements which involve infinitely many, or arbitrarily large finite numbers of, elements. For example, it is easy but boring to write down a first-order sentence which says, 'The number of elements *x* such that *Px* is exactly 10,556,001'. By contrast there is no first-order sentence that says, 'There are infinitesimals'. (The definition of infinitesimals involves the infinitely many elements 1, $\frac{1}{2}$, $\frac{1}{3}$ and so on.) Also we saw that no first-order sentence expresses 'There are just finitely many *x* such that *Px*'. Even if we restrict attention to finite structures, there is no first-order sentence which is true in just those structures for which the set of elements satisfying the formula '*Px*' has an even number of elements.

We have other formal languages in which these things can be expressed. For example, there are languages, known as 'infinitary' languages, in which we can form infinite conjunctions ' S_1 and S_2 and S_3 and… '. The statement that an even number of things satisfy '*Px*' can be written as an infinite conjunction 'There is not exactly one thing *x* such that *Px*, and there are not exactly three things *x* such that *Px*, and there are not exactly five things… '. Infinitary languages can say more than first-order languages; but by the same token it is harder to construct models of theories in infinitary languages, and this makes them less useful for applying model-theoretic arguments in mathematics (see Infinitary logics). The study of different kinds of formal languages and their expressive power is called 'generalized model theory' (see the encyclopedic volume of Barwise and Feferman 1985).

In 1969 Lindström proved some theorems which compare first-order languages with other languages that have greater expressive power. For each signature *S* there is a first-order language $L(S)$; it consists of just those formulas which can be built up from the symbols in *S* using the first-order logical expressions. Suppose that we add some new expressions, for example, quantifiers which express that an even number of things have this or that property. Then each signature *S* will give rise to a richer language $L'(S)$. One of Lindström's results is that if the upward and downward Löwenheim-Skolem theorems (quoted in §3 above) hold for 'elementary equivalence' in the sense of the languages $L'(S)$ instead of $L(S)$, then for every sentence of $L'(S)$ there is already a sentence of $L(S)$ which has exactly the same models. Roughly speaking, any logic which is at least as strong as first-order logic, but not strong enough to distinguish one infinite cardinal from another, must be first-order logic. Lindström's theorems show that the choice of first-order languages as the main languages of model theory was not just a happy accident. But they also raise the question of whether there might be purposes for which first-order languages are not the best choice. We may find such purposes outside mathematics.

7 Truth and possible worlds

The interest of model theory for philosophers rests mainly on two items: Tarski's truth definition and Tarski's characterization of logical deduction. Let us begin with the truth definition. (One philosophical text published in 1992 even defines model theory as the programme of giving a truth definition for quantified predicate logic!)

In model-theoretic versions of Tarski's truth definition we define a relation '$\models$' between structures and sentences; '$M \models \phi$' says that the sentence ϕ is true in the structure *M*. But a typical sentence of English, for example,

(7) Pollution is not the sole cause of the rise in asthma

can be assessed as true or false; no structure is involved.

Some writers contrast absolute truth with model-theoretic truth; the latter is relative to a structure, the former is not. This is a misleading contrast. Truth means the same in model theory as it means anywhere else - the difference lies in the sentences whose truth is being assessed. A typical sentence of a formal language of logic is a schema with schematic variables in it; by itself it does not make a statement. A structure is needed to give meanings to the variables. By contrast, the sentence (7) has no variables, so it needs no structure.

There are some analogues of schematic variables in natural languages. The closest analogues are indexical expressions such as 'I', 'he', these' and 'now' (see Demonstratives and indexicals). To assess the truth of the sentence

(8) He took those

we need to know who he is and what those are. An answer of the form 'If he is Christopher Naples and those are my football boots, then (8) is true' has almost exactly the same content as the statement that the schema '*X* took *Y*' is true in a certain structure.

Nor does (8) determine the time and place referred to. Maybe the sentence was false yesterday but will be true tomorrow. When we assess its truth, we normally take the default time and place - namely here and now; but any account of the truth or otherwise of (8) needs to make some assumption at least about the time. (Strictly there may also be a question about domains of quantification: in (7) what range of possible causes are we considering?)

Some philosophers go further: we need to know whether (8) is taken to be about this world or some other possible world. Even further: there are sentences such as

(9) It is possible that it will rain tomorrow

whose truth now in this world may depend on what is true in other possible worlds. (Is there a possible continuation of this world in which it will rain tomorrow?)

None of these relativities depends on model theory. But model theory offers a format for handling them. Sentence (8) is true in the structure where the possible world is this one, the time and place are as follows, he is so-and-so and those are such-and-such. Oversimplifying a little, sentence (9) is true in possible world *i* if and only if there is a world *j* which is possible relative to *i*, such that 'It will rain tomorrow' is true in *j*. Montague (a student of Tarski) offered a truth definition for substantial fragments of English, using devices of exactly these kinds (see Montague, R.M.). Similar ideas appear in the semantics of many languages used in philosophy and artificial intelligence; see, for example, Modal logic; Tense and temporal logic; Intensional logics. (See also Semantics, possible worlds.)

There may be ontological problems about what a possible world is, but model theory neither adds to nor subtracts from these problems. Most of the structures that one meets in model theory are set-theoretic objects which have nothing to do with possible worlds.

8 Logical truth and consequence

As we saw in the previous section, model theory provides a setting for studying how the truth of a statement is affected if we alter some features of the statement. One traditional way of defining and classifying necessary truths is by noting that they stay true under various kinds of alteration. For example, a necessary truth stays true if we change the possible world; an eternal truth stays true if we change the time; a logical truth stays true if we

systematically reinterpret all the words in it except the logical ones. Classifications along these lines are sometimes described as model-theoretic.

In 1936 Tarski offered just such a definition of logical consequence. On his account, a sentence *S* is a logical consequence of sentences *T* if one cannot reinterpret the non-logical words in *S* and *T* so as to make *S* false and all the sentences of *T* true. He was deliberately vague about which words are logical; he suggested that different choices might lead to different notions of consequence (such as analytic consequence). (See Consequence, conceptions of §5.)

Tarski's definition makes no mention of structures, since he applied it directly to meaningful sentences. To adapt it to a model-theoretic style, we first have to consider formal languages *L* whose symbols are all either logical expressions or schematic variables. Then, as in §4, if *U* is a theory and ϕ a sentence in such a language *L*, we write '$U \models \phi$' to mean that every model of *U* is a model of ϕ. Finally, we say that *S* is a logical consequence of *T* if and only if there are a theory *U* and a sentence ϕ in some such language *L* such that $U \models \phi$ and T, S is a substitution instance of U, ϕ. (We say that a sentence *S* is a 'substitution instance' of a schema ϕ if *S* comes from ϕ by replacing each schematic variable by a meaningful expression - the same expression at all occurrences of the variable; and likewise for a theory.)

9 Model theory in computer science

Computers are good at handling formulas; they are not so good at set theory. So when model theory appears in computer science, it usually has a supervisory role, for example, to describe what computers or robots are supposed to be doing, or how a computer language is intended to work, or what kind of information a database is capable of retrieving.

There is virtually no place in computer science where the class of all models of a theory has any importance at all; in fact it is hard to see how large uncountable structures could possibly be relevant to computing. But sometimes (a) one is interested in the finite models of some theory. For example, these can represent the possible states of a database, or the possible states of a machine during a computation. Sometimes (b) the relevant models are those in which every element is named by a term; these appear as datatypes, or as representations of the behaviour of a machine through time. Another important case is (c) where one is only interested in a single structure, and the question is which sets and relations can be defined in this structure. The model-theoretic semantics of PROLOG is a case in point: the structure in question is the term algebra, and the relations are defined by PROLOG programs. Computer science is open-ended and fast developing, so that other uses of model theory are very likely to appear.

In the 1980s some theoretical computer scientists started to voice a damaging criticism of first-order model theory. The model-theoretic questions which arise naturally in computer science are to do with defining classes of finite structures, or single structures, or relations within a given structure. The classes are defined in terms of the behaviour of a machine or program. For model theory one needs logical languages in which these same classes can be defined. In practice, first-order languages usually turn out to be grossly unsuitable.

For example, if *M* is a finite structure representing the information in a database, and the relations of *M* include a set *P* and a binary relation *R*, then it is easy to compute whether the number of elements in *P* is even, or whether it is possible to get from one given element *a* to another element *b* by a chain: $aRc_1R\dots Rc_nRb$. But neither of these questions can be phrased as a first-order sentence. Or, again, the relations defined by a PROLOG program are rarely definable by first-order formulas; this is because the program can perform recursion, so that the relations are built up inductively.

On the other hand, the properties of first-order logic that Lindström pointed to (see §6), such as the Löwenheim-Skolem theorems, are largely irrelevant for computer science.

No definitive replacement for first-order logic has appeared, but computer scientists have begun to develop some very interesting new languages, for example, languages in which one can express the transitive closure of relations. There is also a thriving branch of model theory devoted to finite structures. Here the interesting classes of structure are, for example, the class of structures which give the answer 'yes' to a certain database query, or the class of those structures which can be picked out by an algorithm in a certain complexity class. (See Complexity, computational; Quantifiers, generalized.)

Models

Of the many kinds of things that serve as 'models', all function fundamentally as representations of what we wish to understand or to be or to do. Model aeroplanes and other scale models share selected structural properties with their originals, while differing in other properties, such as construction materials and size. Analogue models, which resemble their originals in some aspect of structure or internal relations, are important in the sciences, because they can facilitate inferences about complicated or obscure natural systems. A collection of billiard balls in random motion is an analogue model of an ideal gas; the interactions and motions of the billiard balls are taken to represent - to be analogous to - the interactions and motions of molecules in the gas.

In mathematical logic, a model is a structure - an arrangement of objects - which represents a theory expressed as a set of sentences. The various terms of the sentences of the theory are mapped onto objects and their relations in the structure; a model is a structure that makes all of the sentences in the theory true. This specialized notion of model has been adopted by philosophers of science; on a 'structuralist' or 'semantic' conception, scientific theories are understood as structures which are used to represent real systems in nature. Philosophical debates have arisen regarding the precise extent of the resemblances between scientific models and the natural systems they represent.

1 Types of model

Generally, we use models as representations of various things, including desires, hopes and actions, as well as objects and systems in the real world. Not only do many distinct types of thing serve as models, but they also relate in a variety of ways to the world and to us. Fundamentally, to be a model is to serve in a triadic relation: *a person* takes *something* as a model of *something else* (Wartofsky 1979).

One very general meaning of 'model' is as an ideal or paradigm case or exemplar, for example a 'model student', curious and energetic. Here, models serve as ideals towards which people are encouraged to adapt themselves (see Examples in ethics).

Scale models, for example, model aeroplanes and other miniaturized representations, are objects whose properties and relative proportions resemble their originals. Only some properties, however, are the same in the model and the original; usually the construction materials differ, and the functions of the model and the original differ. Still, scale models exhibit the basic relations which enable one thing to stand in for another; in Charles S. Peirce's terminology, the model is an *icon* which represents the original. Icons are different from symbols in their relationship to the things represented: symbols are tied to their originals purely by convention, and any thing can serve as a symbol for any other thing; icons, in contrast, bear some resemblance or similarity to the things that they represent to us. That is, there must be something about the icon itself which is similar or analogous to the object or system of which it is a model. Thus, scale models are a simple kind of iconic model.

Analogue models are usually more abstract than scale models, and resemble their originals primarily in some aspect of structure or internal relations, rather than in materials or appearance. A collection of billiard balls in random motion is an analogue model of an ideal gas in virtue of certain internal relations and interactions among the billiard balls, and not because any thing in the substance or appearance of gas molecules is *like* billiard balls.

Mathematical models are even more abstract than analogue models, in that the objects and their interrelations in the model are all mathematical entities. In the sciences, mathematical models are used to represent a wide variety of real objects and situations.

Finally, there are metamathematical models, which are technical entities used to understand formal systems, such as mathematical systems themselves.

2 Models in metamathematics

In metamathematics (or 'metalogic', the study of the features of formal systems), a 'model' is a structure that makes all of the sentences in a theory true, where a 'theory' is a set of sentences in a language, the various terms of which are mapped onto objects in the system and their relations. Even in metamathematics, though, 'model' is used in several ways: most generally, a model is a special kind of interpretation, where an interpretation of a

theory consists in both the assignment or mapping of terms in the theory to objects, and to a structure, which consists of objects and their relations to one another. More specifically, an interpretation of a language specifies: (1) a domain (universe of discourse), for example, the range of any variables that occur in any sentence in the language; (2) a designation (denotation, bearer, reference) for each name in the language; (3) a function f, which assigns a value in the domain for any sequence of arguments in the domain, for each function symbol in the language; (4) a truth-value for each sentence letter in the language; and (5) a characteristic function for each predicate letter (Boolos and Jeffrey [1974] 1980). In these cases, models are defined as those interpretations under which all the sentences in the theory are true.

Alternatively, models are simply the structures themselves under a specified mapping assignment (where the mapping assignment is taken to be external to the model; Robinson 1965; Tarski 1941). Models can be any kind of structure; in metalogic, models are usually expressed in terms of set theory, but technically any group of objects and their relations could serve as the model for a theory, provided that it displayed the right structure.

For example, take as a theory the sentences: ‘object A is touching object B’; ‘object C is touching object B’; and ‘object C is not touching object A’ (where A, B and C are terms in the theory, and ‘is touching’ is a relation between two or more of the terms). We can easily construct or imagine a structure which ‘satisfies’ or makes true all of these sentences in the little theory: it could consist of three objects in a row, 1, 2, 3, each one touching only the next. Notice that they could be any kind of object, including cats, jars of jam, and so on, or some mixture of these. The *mapping assignment* for the theory might map A onto 1, B onto 2 and C onto 3. (Equally, it could map A onto 3, B onto 2, and C onto 1.) On the usual logical definition, then, the objects 1, 2, 3 constitute one model of the theory, because a ‘model’ is a structure which can be interpreted so as to make all the sentences in a specific theory true (see Model theory).

3 Models in science

Several uses of ‘model’ are standard in the sciences. In each case, models are substitute systems used to investigate and understand the real systems they model. In biology, certain organisms are selected as ‘models’ on the basis of ease of investigation and manipulation; they are investigated intensively, in the hope that the results generalize to other organisms. In biomedical research, for instance, mice are often used as models or stand-ins for studies of drug effects in human beings.

One of the most basic uses of models in physics involves mechanical models of natural processes. Thus, billiard balls in random motion are taken as a model for a gas. This modelling relation does not imply that billiard balls are like gas particles in all respects, simply that gas molecules are analogous to billiard balls. Under the model, some properties of billiard balls ought to be ascribed to gas molecules, that is, motion and impact (the ‘positive analogy’, in Mary Hesse’s terms), while other properties of billiard balls ought not be ascribed to molecules, such as colour and hardness (the ‘negative analogy’). There is also the ‘neutral analogy’, used when we do not know whether the properties are shared; according to Hesse, these properties are what allow us to make new predictions (Hesse 1966: 9). Max Black argued that ’use of a particular model may…help us to notice what otherwise would be overlooked, to shift the relative emphasis attached to details - in short, to *see new connections*’ (Black 1962: 237). N.R. Campbell (1920) claimed that during the development of the kinetic theory of gases, this mechanical billiard ball model of the theory played an essential part in its extension, and thus, that the availability of a working model of a theory is essential to successful theorizing in the sciences. Pierre Duhem, in contrast, argued that such use of models in science was preliminary, optional, and potentially misleading, and that proper scientific theories were expressed abstractly and systematically (Duhem 1914).

Many of the philosophical and scientific discussions about the roles of models in science seem to have mixed together several distinct issues. All participants in these debates agree that there must be some analogy between a model used in the sciences (whether mechanical or not) and the phenomena it is being used to explain. One primary concern was how realistically and completely a model - especially a mechanical model - is supposed to represent the aspect of reality under investigation. Hence, Peter Achinstein (1968) suggests a hierarchy of models based on their ontological commitments: at one end, we have models which are simply supposed to provide possible mechanisms for how natural systems might be operating, while at the other end, we have concrete claims that the real world is thoroughly like the entities and dynamics in the model. In the latter case, the choice of model amounts to a metaphysical commitment regarding the contents of the universe - which things and relations really

exist. A great deal of discussion has thus centred around which of these attitudes - from purely instrumental to strongly ontological - scientists and philosophers should take to the models they use.

The degree to which a model is taken as exactly and adequately representing reality is one of the most significant ways that claims about models in science can differ. What is frequently called an ‘instrumental’ use of models amounts to treating the models as calculating devices; slightly more committed, ontologically, are idealized models, which can be seen as either false-but-handy simplifications of processes in the natural system being discussed, or as approximately true representations of some of the forces operating in the natural system (see Idealizations).

One link between the metamathematical and scientific uses of models lies in the notion of interpretation. In the sciences, models are sometimes used as tools for making sense of theories which are not otherwise immediately comprehensible; a model can thus help the community of scientists articulate and pursue scientific theories. The wave and particle interpretations of light and of quantum mechanics are well-known examples; both the wave and particle models offer ways to understand the theoretical (and well-confirmed) equations, but they present different and incompatible features (see Quantum mechanics, interpretations of).

Finally, models are generally acknowledged to be psychologically valuable to scientists; they serve the heuristic functions of helping scientists envisage very complex systems, and they help simplify inferences about those systems. Even models that are known to be misrepresentations of the real world may sometimes possess these virtues (Wimsatt 1987).

4 Models in philosophy of science

While discussion of the above uses of models in the sciences occupied philosophers of science for many decades, one of their basic assumptions was that models are essentially different from scientific theories. This distinction has come under scrutiny since the 1950s, and much work in recent philosophy of science going under the name of ‘structuralist’ or ‘semantic’ approaches has centred on analysing scientific theories in terms of metamathematical models.

For the middle third of the twentieth century, the reigning logical positivist approaches to science understood scientific theories as ’sets of deductively connected sentences in a formal language’ combined with rules for interpreting some of the terms of that language. In contrast to this linguistic view of theories, some philosophers advocated viewing theories as structures, ‘which are propounded as standing in some representational relationship to actual and physically possible phenomena’ (Suppe 1979: 320). More specifically, scientific theories are understood as presenting models in the metamathematical sense, that is, arrangements of objects and their relations. These structures function as iconic models for the scientists using them: they characterize, in idealized circumstances, the systems that they represent.

Take evolutionary population genetics as an example. Population geneticists tend to present their theories in the form of mathematical models. This means that, given the mathematical models, it is possible to examine the structures that instantiate that theory. Under this ‘semantic approach’ to theories, the focus is on the structures themselves, rather than on an attempt to reconstruct, in some theoretical language, the sentences of the theory, as demanded by the axiomatic and positivist approaches to theory structure. (It remains a matter of debate whether there is an important difference between viewing a theory as a set of sentences and viewing it as a set of models. Some philosophers have suggested that the difference is merely pragmatic or heuristic: scientists sometimes find it more natural to regard a theory one way rather than another, but the two views are in principle intertranslatable. See Schaffner 1993: 99-125.)

This use of metamathematical models is an extension from their use in interpreting formal systems. When models serve as icons, some aspects of the model’s entities and their interrelations are taken to be similar to the phenomena in the natural world that are being investigated. In metamathematics, the more precise notion of isomorphism is central to evaluating the similarity of models. Two models are isomorphic if it is possible to make a one-to-one mapping from each element in one model to an element in the other model, and to make a one-to-one mapping from each relation among elements in one model to a relation among corresponding elements in the other model. While the notion of similarity between model and nature may be intuitive, precision demands that the natural system be represented, abstracted or measured in some fashion, if evaluations of isomorphism between the

theoretical model and nature itself are to be attempted. Typically, measurements or data from the natural system are arranged into a ‘data model’, which provides the basic entities and relations to which the theoretical models are compared (Suppes 1962).

Many questions can be raised about the relations between scientific theories - when understood as models - and the real world. For instance, it is possible that there are relations or entities that appear in the models that have no correspondence in the real world. Alternatively, there may be mechanisms represented in the model which are hypothesized to represent the way the natural world really works; the model might then be interpreted as an approximation or idealization of the real world systems, including mechanisms that we cannot observe directly. Debates among philosophers about ‘scientific realism’ and ‘antirealism’ have centred on the issues of what sorts of inference are necessary, or are justified, by the successful application of a scientific model to the real world (Churchland and Hooker 1985; van Fraassen 1980; Giere 1988; Suppe 1989).

Modernism

As a period in cultural history, modernism usually denotes advanced or avant-garde European and American art and thought, though it has also been used to describe more general social conditions and attitudes. Most historians of literature and the plastic arts - the fields in which the term has most play - date it from the late 1880s to the Second World War. Modernism is thus distinguished from the 'modern' of 'modern history' (understood as anything since medieval history), 'modern life' (popular contemporary attitudes and difficulties), and other broad uses of the term 'modern'. In fact, recognition of the ism *in modernism is a key to understanding it - intense self-awareness being an essential characteristic or value, allied to modernism's complex engagement with avant-garde status. Other values that consistently underpin modernism include a propensity to create 'culture shock' by abandoning traditional conventions of social behaviour, aesthetic representation, and scientific verification; the celebration of elitist or revolutionary aesthetic and ethical departures; and in general the derogation of the premise of a coherent, empirically accessible external reality (such as Nature or Providence) and the substitution of humanly devised structures or systems which are self-consciously arbitrary and transitory.*

1 Epistemic trauma

In religious history, the term modernism still refers narrowly to the late nineteenth- and early twentieth-century movement within Roman Catholicism, and also to analogous developments in Protestantism and reformed Judaism. It constituted an attempt to bring nineteenth-century critical methods, especially those of pragmatism, to bear on subjects formerly regarded as beyond their influence, including the interpretation and application of sacred texts and other doctrines (see Pragmatism). It was condemned as a heresy in 1907 by Pope Pius X. This religious movement shares some of the values of the period in cultural history now commonly referred to as modernism, but remains quite distinct from it.

Given the historical intensity and complexity of the period, it is helpful to abstract several general values that characterize most manifestations of modernism. Such values are not specifically substantive or thematic, but dynamic and structural. They are the dominant qualities that sustain and distinguish the most advanced intellectual activity from the 1880s to the Second World War.

The most readily apparent of these values is that of *epistemic trauma*. This formulation signifies a kind of primary or initial difficulty, strangeness or opacity in modernist works; a violation of common sense, of laboriously achieved intuitions of reality; and an immediate, counter-intuitive refusal to provide the reassuring conclusiveness of the positivist realism that preceded modernism. This traumatic otherness stems in part from a conscious refusal by modernist artists and other thinkers to give their audiences the kind of spatial and temporal orientation that art and literature had been providing since the Renaissance and that had reached a high finish in the mid-nineteenth century, when novelists took pains to provide their 'dear Reader' with temporal and spatial coordinates and when the subject matter of most paintings was generally accessible. In a surprising and historically sudden contrast to this traditional solicitude, the cutting-edge artistic culture of modernism - and much contemporary social and scientific thinking - offered this quality of trauma everywhere. In the painting of Picasso and Braque, in the music of Stravinsky and Schoenberg, in the fiction of Kafka and Faulkner, in the poetry of Yeats and Eliot, the immediate difficulty, the epistemic trauma, is a given of the modernist aesthetic.

The *kind* of difficulty we find in modernist artistic culture resembles the kind of difficulty contemporaneous advances in mathematics and the natural sciences presented to the scientific establishment. In both spheres, the difficulty arises not so much from developments and complications of traditional techniques (what might be called *baroque* difficulty), but more often from what is left out. Relativity Theory (viewed as a vehicle for cultural values, like works of art and literature) provides a notorious example. For many physicists, the initial difficulty of the Special Theory lay in the fact that Einstein found the nineteenth-century hypothesis of an ether 'superfluous', thus radically pruning physics of a laborious but comfortably familiar hypothesis. In all manifestations of the modernist breakthrough, thinking people missed those qualities or techniques on which they had customarily relied for meaning, such as single-point perspective in painting, tonality in music, neutral and uniform time in narrative, and unvarying temporal and spatial reference frames in physics.

Out of this fundamental value of epistemic trauma a number of cognate characteristics emerged. Modernism

quickly developed an affinity to what seemed (when viewed from the tradition of realism) an addiction to gratuitous *difficulty* and *distortion*, either for their own sakes or for the sake of being avant-garde. In fact, discussions of modernism regularly equate it with the avant-garde; and while this equation ignores functional distinctions between the two terms, modernism's commitment to being at the cutting edge, to being shocking and difficult, quickly became a major value. In early modernism, when Cézanne began to depart from single-point perspective in the interest of greater truth to our visual experience of Nature, when Henry James began to introduce ambiguities of motive intolerable to the realist tradition, or when Max Planck introduced energy quanta, the apparent distortions and difficulties, the elitist value of being avant-garde, was not a principal motive or effect. But in a very short period, by the time Picasso had re-represented the human figure in *Les Demoiselles d'Avignon* and Kafka had transformed his protagonist into an insect in *The Metamorphosis* and Einstein had employed obscure mathematics to model a finite but unbounded universe in his General Theory, the antagonistic relation of modernism to popular culture was irreversible: it gradually led to the almost complete bifurcation of serious and popular culture. ' Modern [that is, modernist] art', wrote Ortega y Gasset in 1925 (1968: 5), ' will always have the masses against it. It is essentially unpopular; moreover, it is anti-popular' (see Ortega y Gasset, J.).

2 Reality and observation

One of the most prominent and lasting achievements of modernism in all its manifestations is the devaluation of the premise that we occupy an 'objective' reality, accessible to but independent of human perception. In traditional realism, artists and critics, social thinkers and scientists were thought to make direct statements about this reality, whether it be natural, social or psychological. Modernism essentially turns away from this realist enterprise and towards discussion and analysis of human measurement or observation.

This rich and profound departure is difficult to describe in brief, but an example from modernist physics helps to illustrate it. In the natural sciences, the great model of an objective, constant, external universe was based on Newtonian mechanics. Einstein undermined this coherent and rational structure by redirecting attention from the nature of reality to the nature of measurement, from what was taken to be our direct contact with nature to our observation of it. In his 1905 paper on Special Relativity, Einstein did not ask what time *is*: he asked how we *measure* it. He asked what we *mean* by the time of an event. In Relativity Theory, a measurement is neither a subjective impression (a unique event in a single mind that cannot be fully communicated) nor a constant, necessary description of an independent external object or event. Instead, it may be seen as a kind of middle ground - literally a mediation - between the observer and the observed phenomenon. And this middle ground is the characteristic epistemological location of modernism: its focus is on neither subject nor object but on the act of human observation of a reality presumed but not proved to be external to the observer.

In modernist painting we can see other manifestations of this shift in value. Cubism - with its subject-matter of bottles, tables, shreds of newspaper, musical instruments - clearly deflects our interest from the subject to its representation. In this process it derogates the specific importance of the historically or religiously or sentimentally significant subject (Christ on the Cross, the *Mona Lisa*, *The Rape of the Sabines*) to the problematics of representation, the aesthetics of composition, the formal language. What is significant about Picasso's *Portrait of Ambroise Vollard*, for example, is not the subject (Vollard's distinctive physical features, his support of modernist art, his aesthetic intuition) but how Picasso *presents* Ambroise Vollard. Just as Relativity Theory focused attention away from the nature of reality towards the nature of measurement and observation, so Cubism focused attention away from what was being represented towards how it was being represented.

Similar illustrations of this shift can be found in most movements of modernist art and literature, as well as in modernist developments in philosophy (see Phenomenological movement). But what is of greatest significance here is the liberating nature of this change in values. The practitioners of modernism felt themselves no longer locked into the limiting dichotomies of object and representation, world and observer. They began to move from one side to the other, to explore without interruption the unceasing interaction between the object and its space, or the event and its temporality. The old categories lost their integrity and the artist and subject, or observer and object, came to inhabit a middle ground of observation itself. In this sense of liberation, the modernist model for reality becomes the *field* (as in scientific field models), where observers are also participants (as in cubist painting or quantum theory), where readers help to create the text (as in Kafka's *The Castle* or Faulkner's *Absalom, Absalom!*), or in the many other modernist constructions in which all constituents are interdependent and in which

all participate and interrelate without privilege.

3 Major manifestations

The major literary and artistic movements most often cited as major manifestations of modernism include Post-Impressionism, Fauvism, Cubism, Expressionism, Futurism, Symbolism, Imagism, Vorticism, Dadaism and Surrealism. But such a list will be regarded as necessarily incomplete, and by definition it omits many modernist developments in architecture, philosophy, social science, psychology and the natural sciences - all areas sustained by and manifesting the values discussed above. But a catalogue of movements has the advantage of demonstrating one more value of modernism, that of *reflexivity*: the characteristic of self-awareness and of conscious programmatic direction. We have been regarding modernism as a historical period in high culture and therefore as what Astradur Eysteinsson (1990) calls a ‘cultural force’, but to the extent that each of the movements contained in modernism was aware of its newness and its cohesiveness (that is, of being avant-garde) it can be viewed as an ‘aesthetic project’, the self-conscious endeavour of a group of innovators to further certain values and achieve recognition.

4 Towards postmodernism

Cultural historians and theorists of modernism tend to view what is now called postmodernism in one of two general ways: as part of the original revolutionary gesture in which postmodernism constitutes a late and distinguishable development; or as a new ethos and a new aesthetic (new collection of ‘values’). Preference for one view or the other depends largely on the size of one’s historical canvas, but in either case such discussion proves helpful in defining modernism itself. This is because we can see changes in or departures from the values that constituted modernism, and these changes help to establish their original identities.

In the place of epistemic trauma, postmodernism affirms a denial of prescriptive norms and derogates the *value* of the normative. Where modernism wrestled with the difficulties caused by the absence of universal temporal, spatial, and ethical coordinates, postmodernism adopts without struggle the surreal, bizarre, and meta-natural. Where modernism negotiated the difficult transition from examination of reality to examination of observation, postmodernism accepts the premise that all values are ‘constructions’ on the model of language - local, contained, self-referential. Where modernism sought depth and abstraction, postmodernism turns toward surface and particularity. For what was in modernism a dominant value of ‘order’, postmodernism substitutes ‘design’ and ‘pattern’. Finally, the reflexivity of modernism, its self-awareness, becomes in postmodernism a more radical and complete self-referentiality moving toward visions of total (and so completely free) self-containment (see Postmodernism).

Modularity of mind

A common view in recent philosophy of science is that there is no principled distinction between theoretical and observational claims, since perception itself is thoroughly contaminated by the beliefs and expectations of the observer. However, recent psychological and neurological evidence casts doubt on this latter claim and suggests, instead, that perceptual processing is to a significant extent 'cognitively impenetrable': it takes place in informationally encapsulated 'modules' that cannot be rationally influenced by beliefs or other 'central' cognitive states, or even other portions of the perceptual system.

1 Claims and distinctions

It might appear that what we see depends heavily on what we expect and what we know about the situation at hand. That is how magicians manage to deceive us, and how we sometimes deceive ourselves into hearing and seeing what we have reason to believe is there, missing, for example, typographical errors that we recognize only when they are explicitly brought to our attention. This idea has also been supported by hundreds of experiments carried out in the 1950s, and has been the basis for a widespread view in psychology associated with Jerome Bruner (1957) and referred to as the 'New Look in Perception'. It has also been very influential among philosophers of science such as Hanson (1958) and Kuhn (1962), who have taken for granted that how we perceive the world is thoroughly conditioned by our prior expectations and beliefs (see Observation §§3-4; Perception).

In recent years, however, doubt has been cast on the premise that such processes as visual perception, face recognition, language comprehension are equally 'cognitively penetrable'. The issue is whether the flow of information among cognitive functions is governed by fixed architectural principles, or whether failures to access relevant information in the course of perceptual processing, though widespread, are adventitious (see Cognitive architecture). Despite the widespread acceptance of the idea that perception is contaminated by cognition, a careful examination of the psychological evidence actually favours the view that perception operates autonomously from the system of beliefs and inferences. Jerry Fodor (1983) has argued that certain cognitive capacities seem to be 'modular' or 'informationally encapsulated'. He focuses particularly on what he calls 'input systems', which include cognitive systems for perception and language (see Fodor, J.A.).

To make Fodor's views clear, however, we need to make some critical distinctions.

(1) The distinction between 'what we see' and what we come to believe about what we are looking at.

(2) The distinction between perceptual and post-perceptual effects such as those that depend on the exigencies of memory and decision processes, including the decision to make a particular response. (Sometimes post-perceptual effects can be mathematically factored out using a signal-detection method that allows one to separate 'detection' from 'response selection' effects - the latter of which clearly depend on beliefs and utilities; see Samuel (1981).)

(3) The distinction between *extra*-modular *cognitive* penetration of perception, and other top-down but *intra*-modular effects. It is clear that how certain local features are perceived may depend on more global aspects of percepts - for example, how a phoneme is perceived may depend on word-level acoustical perception - but these generally are not effects of cognition but of broader aspects of perception. There are plenty of examples in vision where how a local feature is perceived depends on how the larger scene is perceived, but where the latter itself is insensitive to more general beliefs and inferences.

2 Evidence

Perhaps the most striking evidence for modularity of perception is the imperviousness of various illusions to knowledge: even when you have every reason to believe that something you are seeing is an illusion, you cannot make the illusory percept disappear. Moreover, perception appears to have a logic all its own: if you see some part of a pattern in a certain way you will automatically tend to see other parts of the pattern in a compatible way. For example, if you see the reversing Necker cube (see Gestalt psychology §2) in one orientation you will see each of its edges in the appropriate relative location, and will even see the apparently-further face as bigger.

There is a great deal of evidence for the existence of pre-recognition stages in perception that are clearly immune

to cognitive influences. (Stich (1978) calls the output of such stages, characterized by their lack of 'inferential promiscuity', 'sub-doxastic states'.) In addition there appear to be even finer submodules within the visual system. For example, there is considerable independence of the colour perception system, the motion detection system, and the form recognition system. Stereo depth and motion-induced depth perception (so-called kinetic depth effect) do not require prior recognition of form. Examples of this sort are commonplace, and all point to there being architectural constraints on communication among parts of the visual system and between the visual system and the rest of cognition. In the face of this kind of evidence it appears that at least the principle of modularity is well established, even when the exact locus of the modules and the type and extent of encapsulation may be open to debate.

Related evidence is also provided by various pathologies of perception. In these cases of dysfunction (due to brain damage or illness) patients frequently show signs of dissociation of functions, providing clear evidence that a certain function, which is absent in particular patients, is not required in order to accomplish some other function, which remains intact in those patients. For example, colour-blindness can occur without form-blindness.

Although functional decomposition is commonplace, it is the special case of the dissociation of much of perception from the rest of the cognitive system that is of particular importance to philosophy. What such cognitive impenetrability suggests is that there is reason to distinguish between *data*-driven and *theory*-driven aspects of perception. And if that is the case, then the observation/theory distinction may have some empirical support after all, and one of the arguments for epistemological holism may also be undermined. (See the exchange between Fodor (1984; 1988) and Churchland (1988) for discussion of this issue.)

Mohist philosophy

Mohist philosophy describes the broad-ranging philosophical tradition initiated by Mo Ti or Mozi (Master Mo) in the fifth century BC. Mozi was probably of quite humble origins, perhaps a member of the craft or artisan class. Early in life, he may have studied with followers of Confucius. However, he went on to become the first serious critic of Confucianism.

Mozi's philosophy was part of an organized utopian movement whose members engaged in direct social action. He was a charismatic leader who inspired his followers to dedicate themselves to his unique view of social justice. This required them to lead austere and demanding lives, as he called upon them to participate in such activities as the military defence of states unjustly attacked.

Mozi is arguably the first true philosopher of China. He was the first to develop systematic analyses and criticisms of his opponents and present carefully argued positions of his own. This led him and his later followers to develop an interest in and study of the forms and methods of philosophical argumentation, which contributed significantly to the development of early Chinese philosophy.

Mozi saw ideological differences and the factionalism they spawned as the primary source of human suffering, and he hotly criticized the familially-based ethical and political system of Confucius for its inherent partiality. In its place he advocated three basic goods: the wealth, order and the population of the state. Against the Confucians, he argued for jian'ai *(impartial care).* Jian'ai *is often translated as 'universal love', but this is misleading. Mozi saw the central ethical problem as an excess of partiality, not a lack of compassion; he was interested not in cultivating emotions or attitudes, but in shaping behaviour. He showed remarkably little interest in moral psychology and embraced an extremely thin picture of human nature, which led him away from the widely observed Chinese concern with self-cultivation. His general lack of appreciation for psychological goods and the need to control desires and shape dispositions and attitudes also led him to reject the characteristic Confucian concern with culture and ritual.*

Mozi believed human beings possess an extremely plastic and malleable nature, and he advocated a strong form of voluntarism. For several different reasons, he believed that people could be induced to take up almost any form of behaviour. First, he shared a common early Chinese belief in a psychological tendency to respond in kind to the treatment one receives. He further believed that, in order to win the favour of their rulers, many people are inclined to act as their rulers desire. Those who do not respond to either of these influences can be motivated and controlled by a system of strict rewards and punishments, enforced by the state and guaranteed by the support of Heaven, ghosts and spirits. Most important of all, Mozi believed that rational arguments provide extremely strong if not compelling motivation to act: presented with a superior argument, thinking people act accordingly.

The social and political movements of the later Mohists lasted until the beginning of the Han Dynasty (206 BC). They continued Mozi's early interests and developed sophisticated systems of logical analysis, mathematics, optics, physics, defensive warfare technology and strategy and a formal ethic based upon calculations of benefit and harm. All the philosophical concerns of the later Mohists can be found in the early strata of the Mozi, and seem to reflect the teachings of the tradition's founder.

1 Nature of the work

The present text of the *Mozi* consists of fifteen books unevenly divided into seventy-one chapters, eighteen of which are now lost (for a complete list, see the table of contents of Y.P. Mei's translation (1929)) (see Mozi). Contemporary scholars tend to divide the book into five parts: the Epitomes (chapters 1-7), Essays (8-39, seven of which are lost), Logical Chapters (40-5), Dialogues (46-50) and Military Chapters (51-71, nine of which are lost). The Epitomes are clearly of later origin and, in several cases, of questionable provenance. The Essays are the core of the text and offer a complete and consistent account of Mohist philosophy. Depending on one's view, they present either ten or eleven different themes: 'elevating the worthy', 'identifying with one's superior', 'impartial care', 'against aggressive warfare', 'economy in expenditures', 'economy in funerals', 'heaven's intention', 'explaining ghosts', 'against music', 'against fate' and 'against Confucians'. For both textual and philosophical reasons, the last does not seem to fit with this group and will not be considered here as part of the Essays' corpus.

Originally there were three separate versions of each of the remaining ten themes, which are thought to represent three different sects of later Mohism. The existence of three later Mohist sects is attested to in collateral sources, though we know very little about their distinctive natures or their relationship to these chapters. Graham (1985) argued for a rearrangement of the chapters, which he believed revealed distinct doctrinal differences, but his analysis remains controversial and the philosophical differences he identified are not significant. The repetitive and unadorned style of these triadic chapters has led several scholars to speculate that they may be different versions of recorded sermons or lectures, or part of an original oral tradition. In any event, they present the central doctrines of early Mohist philosophy and may even be an accurate record of the teachings of Mozi himself. Later Mohists tend to write in a similarly unembellished fashion but ostensibly for a definite purpose: they sought to eliminate all stylistic flourish, believing it could only obscure the weakness or interfere with the strength of an argument.

The Dialogues seem to be of slightly later date and, like the *Analects* of Confucius (see Confucius), record conversations between Mozi and various disciples and opponents and stories about his exploits and travels. The Logical Chapters and Military Chapters both appear to be of considerably later date, and develop in systematic fashion Mozi's early concern with the forms of argumentation and the practical aspects of defensive warfare.

2 Central philosophical doctrines

Like Xunzi (and also like Thomas Hobbes), Mozi described a state of nature which is an unfulfilling war of all against all. However, he did not see this state as the result of our having shared and unruly desires which lead us into competition and conflict over scarce goods. For Mozi, human beings are led to fight with one another because they hold individual and irreconcilable notions of what is *yi* (right). The fundamental problem is a fragmentation of values. Hence the most pressing task is to get people to agree on a single notion of what is right. Mozi believed that the right consists in maximizing the collective well-being of the group: those who support and work for this unified goal put the common good ahead of their personal well-being and hence are, by definition, the most 'worthy' people for public office. Thus they deserve to be promoted to positions of authority in the state and deferred to by those they supervise. Mozi argues for these ideas in the first two groups of synoptic chapters: 'Elevating the Worthy' and 'Identifying with One's Superior'.

Mozi believed that the control and redirection of human desires was not a problematic task, nor did he believe one needed to develop virtuous attitudes and dispositions in order to behave ethically. Since he saw no need to develop or shape the self through ritual practice, introspection or insight, he was not, like most early Chinese philosophers, a self-cultivationist (see Self-cultivation in Chinese philosophy). Nevertheless, he was not a Hobbesian-style contractarian either. He believed that people could be influenced to adopt a non-competitive mode of behaviour through a variety of means. Hence, in theory at least, he avoided the difficulties associated with problems like the prisoner's dilemma (see Rational choice theory §3).

Mozi relied upon four basic techniques to influence people's behaviour. First, he appealed to a rather mechanistic version of the generally accepted early Chinese belief that people are inclined to respond in kind to the treatment they receive. Second, he believed that many would act as their ruler desired, simply to curry favour. Third, he advocated a system of well-defined rewards and punishments designed to move people away from certain types of behaviour and toward others. Consistent with his moral psychology, his list of rewards and punishments contained only material goods, with the single exception of 'honour' or 'prestige'. In this respect he anticipated later Legalist philosophers such as Han Feizi, who like him were not self-cultivationists and who relied upon the power of the state to shape behaviour through a publicly-proclaimed system of rewards and punishments (see Legalist philosophy, Chinese). However, Mozi differed from these later thinkers in believing that his system of rewards and punishments had Heaven's active and direct support (see Tian). In the seventh group of synoptic chapters, 'Heaven's Intention', he claimed that Heaven directly intervenes in human affairs to reward and punish, and in the eighth group, 'Explaining Ghosts', he argued that ghosts and spirits act as Heaven's agents to ensure that justice is upheld.

Mozi's fourth basic approach to influencing people's behaviour entailed an extreme form of voluntarism. He believed that most, or at least many, people could simply take up a form of behaviour and would do so if they were given good reasons for adopting it. Mozi argued that anyone who truly understood that a given form of behaviour does indeed maximize the common good (as he understood it) would immediately act accordingly. This belief in

the inexorable power of argument is of a piece with his sparse moral psychology and belief in the plasticity of human nature, and helps to explain his active and persistent interest in the forms and method of philosophical debate.

3 Central philosophical doctrines (cont.)

The most important philosophical position Mozi sought to establish is *jian'ai* (impartial care). He argues for this view in the third group of synoptic chapters, which take this theme as their title. Impartial care is the key to Mozi's philosophical system and the basis for many of his other teachings. He believed it is the only way to correct the destructive tendency to form factions and show preference to oneself, one's family and one's group. The unity that results when everyone adopts a policy of impartial care optimizes the wealth, population and order of the state.

Mozi often asserts or assumes that maximizing these collective goods will result in maximizing individual good. At times he does argue for this connection: for example, he argues that a truly filial man will embrace impartial care as the best way to serve his parents, wife and children. Like Confucius, Mozi develops his ethical philosophy from the perspective of groups rather than individuals. Here, their major difference is that for Confucius the family is primary while for Mozi the collective or state is most important. Impartial care does not entail egalitarianism. Mozi saw *jian'ai* as perfectly compatible with a strict social hierarchy and an absolute monarchy. Like almost every early Chinese philosopher, he appealed to a past golden age when his own proposed policy had been actually practiced. Such an appeal was thought to show first, that his theory was feasible, and second, that the practice of this theory was the reason for the success of earlier society (see History, Chinese theories of).

Mozi further believed that Heaven itself practised impartial care, and desired human beings to do the same. He argued for this view in the seventh group of synoptic chapters, 'Heaven's Intention'. In early China, it was widely held that if one could discern and follow Heaven's plan, one would be in accord with a pattern inherent in the universe itself, which would normally lead to ease in action and to success. Mozi accepted this general idea and insisted that following Heaven's plan would guarantee reward. As he argued in the tenth group of synoptic chapters, 'Against Fate', to believe anything less was to succumb to a pernicious form of fatalism. Since Heaven practises impartial care and is omniscient and all-powerful, good people will always be rewarded for their good deeds and bad people will always suffer punishment. Since the ideal state is modelled on the pattern of Heaven, rewards and punishments will be the strict policy of any just ruler.

Another important and related Mohist assumption is that the good is always useful, in the sense of directly producing material benefit for the world. One can see this throughout Mozi's philosophical teachings. Impartial care is good and directly benefits the world. A belief in 'fate' is bad and entails the negative consequences of complacency and defeatism. This linkage of the good with the useful occasionally led Mozi to conflate the notions of the 'good' and the 'true'. For example, as part of the justification for his claim that ghosts and spirits exist, Mozi argues that believing in their existence is useful: it influences people to be ethical. It is tempting to claim that Mozi is merely relying on a 'useful fiction' in order to achieve a greater good, but such an interpretation must ignore or explain away considerable textual evidence supporting his belief in ghosts and spirits, in particular the entire eighth group of synoptic chapters. Such a view must also ignore or explain away Mozi's belief that Heaven guarantees that there is absolute justice in the world. Finally, such an interpretation must ignore the fact that Mozi did not support this claim with an appeal to its utility alone. In fact, he employed three basic tests for any doctrine.

In the last group of synoptic chapters, 'Against Fate', Mozi presents the three tests that any theory should pass. It is significant that the word translated here as 'test' is literally a gnomen, an astronomical instrument used to determine the direction of the rising and setting sun. Thus Mozi's three tests allow one to orient oneself to the way things are in the world: 'We must set up a standard of judgement, for to try to speak without a standard of judgement is like trying to establish the direction of sunrise and sunset with a revolving potter's wheel…' (*Mozi* 35, in Watson 1963: 117-8). These three tests are precedent, evidence and utility.

The first test is an appeal to the policies and beliefs of idealized past sages. While the Mohists recognized the need for technological innovation, they share the common Chinese belief that the important theoretical discoveries regarding self and society were all known to a select group of past sages (see Chinese Classics). The Mohists tended to appeal to the earlier sage-king Yu rather than to the favourite Confucian exemplar, the Duke of Zhou, but

they often appealed to the same individuals as the Confucians did, ascribing to them different beliefs and practices. Any proffered theory ought to find precedent in the practices and beliefs of these former sages. Such precedent establishes both its feasibility and efficacy. The second test is an appeal to commonly held beliefs and practices, something like an appeal to 'common sense'. Any theory that is not supported by evidence derived from the 'eyes and ears' of the people is not to be accepted. Finally, the third test concerns measuring the consequences the theory has for the common good: the aggregate wealth, order and population of the state. As Graham has pointed out (1989: 37-8), the theories presented in the ten synoptic chapters themselves are all supported by these three tests. However, for most, only the first and third tests are applied. The second test is only employed to establish Mozi's claims regarding the existence of ghosts and spirits and the non-existence of destiny.

Mozi did not rank the three tests in any way. While it is true that he often pointed to the purported good consequences of his proposals, this may have been motivated more by rhetorical than logical considerations. It seems most reasonable to believe that for Mozi and his followers the truth of their theories was strongly over-determined: it could never be the case that the precedents of the sages or the common-sense views of the people could conflict with optimizing the collective good.

The three tests can be seen as related to another principle which Mozi developed and employed both to criticize his opponents and to establish his own case, namely, consistency. For example, in condemning aggressive wars Mozi argued that someone who steals one peach or kills one person is recognized as guilty, but those who steal and slaughter whole states are not (this argument was later parodied in the *Zhuangzi*). Here the call to consistency is combined with an appeal to common sense. In another chapter from the same group, Mozi argues that while aggressive warfare has worked for a few states, it comes only at the expense of many others. To claim that, as a principle, aggressive war is right '…is rather like the case of a doctor who administers medicine to over ten thousand patients but succeeds in curing only four' (*Mozi* 19, in Watson 1963: 59). Here the principle of consistency is combined with an appeal to the common good.

4 Central philosophical doctrines (cont.)

The remaining four groups of synoptic chapters, 'Against Aggressive War', 'Economy in Expenditures', 'Economy in Funerals' and 'Against Music', are all reactive policies. The first is directed against the general practice of rulers in his time, and the last three are specifically aimed at his Confucian competitors. While motivated as criticisms, these chapters are perfectly consistent with and representative of Mohist philosophy as a whole. All are justified by appeals to the three tests of a doctrine as well as Mozi's principle of consistency. Moreover, they all reveal his characteristic lack of appreciation for the value of psychological goods.

For example, in 'Against Aggressive War', Mozi deploys his full array of arguments: aggressive war fails all three tests and the asymmetry between the condemnation of killing one person and the celebration of killing whole populations violates his principle of consistency. As Lowe (1992: 18) has noted, Mohists were not really pacifists although they are often described as such. Mozi and his followers had a just-war theory and participated in what they regarded as ethically warranted warfare, but, as these chapters reveal, they were adamantly opposed to wars of expansion. What is striking in Mozi's searing and well-argued condemnation of aggressive war is the complete absence of descriptions of the horror of war. All Mozi seems to see is the unprofitability of war. His overriding concern with *li* ('benefit' or 'profit') led him to ignore a broad range of psychological goods and harms (see War and peace, philosophy of §1).

This absence of any consideration of psychological consequences is manifested throughout the remaining three groups of synoptic chapters, in which Mozi argues against the elaborate cultural embellishments, funeral practices and court music advocated by Confucians. While a reasonable case could be made against extravagance in any of these pursuits, Mozi does not acknowledge the possibility that such activities, properly moderated, might possess some value. He not only rejects the idea of their inherent value, he does not even consider that they might be instrumentally valuable in the task of shaping human behaviour.

Mozi's complete rejection of psychological goods shows that it is inaccurate to describe him as a utilitarian, at least in the classical sense (see Utilitarianism). He is not working to optimize aggregate pleasure and pain. In the absence of this classical utilitarian concern, it is at first glance difficult to see what justification or motivation Mozi can provide to support his ethical theory: in particular his call for impartial care. However, there is a clear

foundation for his ethical vision: his belief that it accords with or, more accurately, mirrors what Heaven intends (Lowe 1992: 132).

Mozi often appeals to a kind of divine sanction as justification for his ethical views, but it is important to understand that his notion of Heaven is not strongly theistic. While Heaven has intentions, these are a set of natural patterns or forces in the world, not acts of will originating from an independent agent standing outside the world and sustaining it. Heaven did not create the world and, while Heaven provides a model for human activity by showing impartial care for all, it is always reactive in showing its support or displeasure. Heaven is not a personal God who loves individuals, but a force which ensures that certain actions are met with appropriate reactions.

The relationship between human beings and Heaven is quite revealing and representative of Mozi's general orientation. The first point to note is that a person's attitude toward Heaven is not devotional: there is little or no emotion - never mind passion - involved. The intercourse between people and Heaven is a simple form of behaviour, a kind of transaction. There is nothing mysterious or awe-inspiring about Mozi's Heaven. As long as people act in accordance with the Heavenly pattern of impartial care, they can be assured that they will receive Heaven's support. If they deviate from this plan, they act against Heaven and will not escape its punishment.

Confucius believed that Heaven was on the side of good people and that acting in accordance with Heaven's will was the only way to realize certain personal and social goods. However, he also believed that no one was guaranteed Heaven's support. Heaven sometimes acts in ways that were inscrutable to human beings and this should not affect the way one behaves. He also believed that good people tend to have a strong influence on others that elicits from them reciprocal acts of goodness, and that this is the only legitimate way to influence others to be good; but again, one could never be guaranteed that such reciprocity is forthcoming. In either case, there was something fundamentally wrong with attempting to manipulate Heaven or humans by consciously working these natural tendencies to personal advantage. Even self-consciously pursuing virtue ran the risk of tainting one's character with thoughts of self-aggrandizement and pride (see Confucian Philosophy, Chinese).

Mozi's philosophy opposed almost all of these fundamental tenets of Confucius' thought. He believed that if there were not a direct and immediate guarantee of reward or punishment, the idea that Heaven supported ethical conduct was empty. If Heaven proved to be unknowable or unreliable, people would lose all faith in affecting their future improvement and would resign themselves to whatever they perceived as their fate. In a similar way, Mozi believed that people could be motivated to 'care' for others only by embracing a wholly impersonal system of the equitable distribution of material goods which guaranteed them treatment in kind. Mozi and his followers could never see virtue as, in any way, its own reward (see Virtue ethics).

5 Later Mohist philosophy

The later Mohists developed and extended the philosophical interests of their tradition's founder. Some of their most important advances came in what might be described as the science of argumentation (see Logic in China). They laid out definitions of necessary and sufficient conditions, inference and a priori, developed a version of the law of excluded middle, and analyzed and discussed such notions as universals and particulars. However, the way they approached these issues was distinctive and in some cases significantly different from the way early Greek thinkers worked (see Zeno of Elea). The Mohists were more empirical than abstract in their approach. They were trying to sort out certain problems; their work bore a greater resemblance to careful accounting, taxonomy or cartography than theoretical mathematics. It is significant, as Graham (1989: 60) has pointed out, that although the later Mohists took geometry as paradigmatic of clear and exact thinking, they never developed a discipline of geometric proof. They were content simply to illustrate that certain relationships and regularities obtained by appeal to geometric paradigms.

Owing at least in part to the nature of the classical Chinese language, where many logically significant distinctions within sentences such as number and tense are unmarked, the later Mohists did not develop formal logic. Like most Chinese philosophers, they began with *ming* (names) and sought to map these onto the things and events in the world in a clear and consistent fashion. Working in this way, they built up terms and strings of names to form sentences which would then either be 'so' (*ran*) or 'not so' (*buran*) of a given case. They noticed and sought to make clear that semantic differences - particularly those arising from the idiomatic meanings of compound terms - generate considerable problems when one attempts to draw parallels and analogies between sentences and arrange

them into classes.

One well-known example is the later Mohist treatment of the parallel sentences: ‘Robbers are people’ and ‘Killing robbers is not killing people’. While the second sentence simply appears false in English, this is because it has been rendered literally, thereby obscuring the semantic ambiguity of key terms. In Chinese, *shadao* (killing robbers) has the sense of ‘executing robbers’, while *sharen* (killing people) has the sense of ‘murder’. Thus the immediate sense of the sentence is something like, ‘Executing robbers is not murdering people.’ Many related cases were also studied, such as the sentences, ‘Increasing the number of robbers is not increasing the number of people’ and ‘Caring for robbers is not caring for people.’

The later Mohist approach to these problems is largely an attempt to define criteria for class membership. On the primary level of things, they sought to establish definite and distinct *lei* (‘categories’ or ‘classes’) based on observable similarities and differences. They were not seeking Platonic essences nor even the generic definitions of Aristotle; they were thoroughgoing and somewhat naïve nominalists (see Nominalism). Nevertheless, since they insisted on a strict accounting of what does and does not merit inclusion in a given category, they avoided many problems that have bedevilled Western philosophy concerning the notion of what is ‘true’, while still having a workable and functionally equivalent concept. They used a similar approach on the level of sentences, which they viewed as strings of names.

In order to argue for the similarity of separate cases, the later Mohists also developed the notion of ‘inference’ (*tui*). Again, Graham (1989: 150) is highly instructive in noting that the later Mohist notion of inference differs from induction, whereby one moves from the known to the unknown. Rather, it is used to argue for the *actual* similarity between cases. At their most abstract, the later Mohists employed an established category as a kind of template to assess the status of some actual thing or situation, to see whether or not it warrants inclusion within a given set. As is clear from the examples involving ‘people’ and ‘robbers’ presented above, class membership can be critically important (see Categories).

Mohist ideas regarding ‘categories’ and ‘inference’ had a profound effect on early Chinese philosophy. For example, they were adopted and played a major role in the thought of Mencius. As well as using Mohist logical terms of art, Mencius adapted them, in some cases enlarging their sense, to make specific points critical to his philosophical position. For example, he argued that the sage is the same in kind (*lei*) as other human beings (*Mengzi* 2A2, 6A7). He further argued that in order to ‘fill out the category’ of human being, one must ‘infer’ (*tui*) or ‘draw the analogy’ between paradigmatic cases of moral action and relevantly similar ones (*Mengzi* 1A7, 2A9). In a justly famous passage (*Mengzi* 1B8) strongly reminiscent of the Mohist examples presented above, Mencius argues that past sages who rebelled against and killed their evil rulers did not perpetrate the crime of regicide, since these rulers were not ‘kings’ but rather ‘mutilators’ and ‘outcasts’.

In the later Mohist material, there is a discussion of the relationship between benefit and harm and liking and disliking that appears to present a genuinely utilitarian ethic. However, closer inspection reveals that what is of value are not raw states of pleasure or pain nor even more lofty feelings of altruism or compassion. What is ‘liked’ or ‘disliked’ is determined a priori by ‘the sage’, who enjoys what produces the greatest collective good for the state. What is new is the explicit use of a functionally defined ideal observer, the sage. Earlier Mohists appealed to the authority of sages, but their appeal was always to actual past sages.

This was not the only change that later Mohists made in their ethical theory. In *Mengzi* 3A5, we find the Mohist Yi Zhi proposing a modified form of voluntarism (Nivison 1980). The debate begins with Mencius criticizing Yi Zhi for advocating frugal burials while at the same time providing lavishly for the burial of his own parents (essentially accusing Yi Zhi of failing to meet his own Mohist criterion of consistency). Yi Zhi replies first by quoting a classical passage (thus invoking the third ‘test’ and employing an appeal the Confucians themselves should accept), which he presents as supporting the Mohist teaching of ‘impartial care’. He then argues that while such care is the ideal and ultimate end, it naturally begins in the home. We start by caring for our parents and then, by applying the teachings of Mozi, we are to universalize this feeling until we care equally for all. Thus Yi Zhi softens the strong voluntarism of early Mohism and attempts to ground it in a Mencian-style appeal to innate moral inclinations.

Although they shared many important assumptions and concerns with other early Chinese thinkers, the later

Mohists were remarkably different in their approach. They did not seek for wisdom guided by the contemplation and synthetic grasp of historical paradigms, nor did they turn to intuitions about or reflections upon human nature. They trusted in careful observations and precise analyses with the aim of attaining a comprehensive and systematic understanding. The later Mohists were highly successful for several centuries but then, for reasons that remain obscure, their movement died out rather suddenly around the beginning of the Han Dynasty (206 BC). Nevertheless, they live on in at least one sense, in the profound and pervasive effect they have had on the Chinese philosophical tradition.

Molecular biology

Molecular biology is the study of the structure, function and kinetics of biologically important molecules. Historically, molecular biology has often been identified with molecular genetics. Similarly, the chief philosophical concern with molecular biology has been the possibility of the reduction of classical genetics to molecular genetics. The nature and boundaries of molecular biology, however, are themselves disputed. To some, molecular biology seems to be a morass of molecular details without any overarching theory. To others molecular biology is an integrated interlevel theory. How philosophical issues, such as reduction, are addressed can depend importantly on how molecular biology is initially characterized.

1 Molecularizing biology

Although molecular biology can be broadly defined as the study of the structure, function and kinetics of biologically important molecules, the origins of molecular biology are usually traced back to two specific research traditions: the informational school and the structural school. This historical approach has been strongly disputed. Nevertheless, it provides a starting place for historical analysis.

The informational school is identified with the study of bacterial viruses (bacteriophage or phage) begun in the late 1930s by Max Delbruck, Salvador Luria and Alfred Hershey. The phage group, as they would come to be known, took as its goal the elucidation of the physical basis of heredity through careful experimental study of virus self-replication within bacterial hosts. The problem of replication was itself a means of investigating how molecules could store and transmit genetic information. Chromosomes were the accepted material basis of heredity and were known to be mixtures of nucleic acids and proteins. Proteins, by virtue of their known linear arrangement of specific units, were thought to be better candidates for information storage and transfer than were nucleic acids. This emphasis on proteins was overthrown by Alfred Hershey and Martha Chase’s experiments published in 1952 demonstrating that deoxyribonucleic acid (DNA) alone was injected into host bacteria. With the use of their Waring blender, Hershey and Chase had ingeniously shown that DNA, not protein, was responsible for virus replication.

At roughly the same time that the informational school was starting out in the 1930s, the structural school began extending traditions in structural chemistry to the study of biological molecules. In the USA, Linus Pauling used his expertise as a structural chemist to explain the helical structure of polypeptides essential to important biological proteins such as hemoglobin and myoglobin. In England, W.T. Astbury and J.D. Bernal began using X-ray crystallography to study the internal structure of proteins. This programme was expanded as the Cavendish Laboratory at Cambridge and King’s College in London began X-ray diffraction studies of biological molecules.

These two schools of thought came together in the 1950s with the collaboration of James Watson and Francis Crick. Watson’s knowledge of phage genetics and Crick’s knowledge of X-ray crystallography both contributed to their now famous discovery of the double helical structure of DNA in 1953. The two-stranded model of DNA with its complementary base pairs explained the structural features of the DNA molecule and suggested how DNA could both store and transfer information.

The neat division of the origins of molecular biology into these two schools has been disputed on historical as well as historiographical grounds. The structural and informational schools were introduced as historical categories in the 1960s as biologists struggled to define molecular biology. Gunther Stent, a member of the phage group, strongly identified the phage group with the origins of molecular biology. John Kendrew, who won the Nobel Prize in 1962 for determining the structure of myoglobin, had a completely different experience of the emergence of molecular biology. Kendrew introduced the idea that there were two schools. Gunter Stent agreed and extended Kendrew’s analysis in his reply. At the time Kendrew and Stent were writing, the emphasis in molecular biology was on integration of structure and function in biological molecules à la Watson and Crick. In effect Kendrew and Stent projected the reality of 1960s molecular biology into the past and in doing so created a history that legitimated present practice (Abir-Am 1985).

The structural and informational schools do not encompass the origins or the present state of molecular biology. It is not even clear to what extent the loose association of individuals doing structural work on biological molecules

can be considered a school. The origins of molecular biology as well as its current practice represent a much more diverse array of traditions.

Molecular biology, as it was first defined by the National Science Foundation in 1954, covered a wide variety of biological phenomena, such as the:

> identification and structure of particulate matter such as mitochondria, chloroplasts, chromosomes, viruses, enzyme structure and kinetics - chemistry of coenzymes, electrochemical phenomena, membranes and fibers, solid and liquid state phenomena, reactions of proteins - long range forces, mathematical approaches to biological problems
>
> (quoted in Zallen 1993: 81).

Clearly, molecular biology could be seen as drawing on long-standing traditions in biochemistry, cell biology and bioenergetics, as well as those in phage research and structural chemistry. The history of molecular biology may be dominated by the history of molecular genetics, but the practice of molecular biology is and has been much more diverse.

2 Interlevel theories

As philosophers tried to come to grips with molecular biology and particularly the question of the reduction of classical genetics to molecular genetics, they were faced with the problem of how to characterize the structure of molecular biology (see Genetics §4). While some thought of molecular biology as a scientific theory, characterized as a set of general laws or a set of axioms, others began to conceive of molecular biology in terms of interlevel theories and practices. These different approaches to theory structure can have important consequences for other philosophical issues, such as reduction.

Kenneth Schaffner has argued that most biomedical theories, including molecular biological theories, should be thought of as a series of overlapping interlevel temporal models (Schaffner 1993a, 1993b). This proposed analysis treats theories as families of models, as polytypic aggregates with some specified core characteristics. The entities represented by these models are usually undergoing some process and so are temporal. The theory is an interlevel theory because the entities represented by the theory can be grouped according to level of aggregation. Entities at one level of aggregation may share parts with entities at lower levels, but the defining properties of the entity at the higher level require organizing principles not found at the lower level.

It is often assumed that the successful reduction of a higher level theory to a lower level theory will result in the replacement of the higher level theory by the lower level theory. This strict reduction-replacement approach requires that the lower level theory use only lower level terms and entities. Schaffner’s interlevel theories require that this strict model of reduction-replacement be relaxed to allow partial or patchy reductions as a result of more complex connections between parts of different interlevel theories. With the complex interlevel processes considered in molecular biological theories, one should not expect complete unilevel reduction of a higher level theory to a lower level biochemical theory, which itself is often an interlevel theory. Molecular biological explanations, according to this view, are facilitated by partial reductions and causal generalizations regarding the temporal sequence of events represented by the relevant model (Schaffner 1993b).

3 Practices

Schaffner’s appreciation of the complexity of molecular biology is shared by Sylvia Culp and Philip Kitcher’s analysis of molecular biology in terms of practices. A practice consists of a language used by the scientific community of interest, the set of statements that community accepts, the set of questions they take to be important, the patterns of reasoning they use to answer those questions, the methodological directives or standards they use to evaluate solutions and experiments, and a set of experimental techniques (Culp and Kitcher 1989). Using this account of practices, Culp and Kitcher argue that the contemporary practice of molecular biology can be understood in terms of a hierarchy of questions concerning why some biologically important process occurs, and how accepted statements and experimental techniques contribute to the solution of that problem. The interlevel complexity described by Schaffner is captured in Culp and Kitcher’s practices by the hierarchy of questions. In the case of cell biology, for instance, Culp and Kitcher start out with the fundamental question of ‘how do organisms move?’. This question is then followed by the supposition that ‘motion requires contraction and extension of

muscles' and the related question of 'how do muscles contract?'. This question is then followed by the supposition that 'muscle cells contain actin and myosin' and the related question of 'how do actin and myosin contribute to the contraction of a cell?' (Culp and Kitcher 1989). This nested set of questions leads to a nested set of explanations. Cellular theories of motion do not reduce to molecular biology within this hierarchy; instead the explanations of the action of myosin and actin extend the cellular explanatory scheme. An explanatory scheme is a schematic argument with specific filling instructions.

What makes explanatory extension different from strict reduction-replacement is that it allows different parts of an explanatory scheme to be extended in different directions by different theories. Molecular biology does not provide the only route for explanatory extension and it is not the case that all explanatory extensions will ultimately end with molecular biology (Kitcher 1984). Schaffner's complex reduction-replacement model with its partially overlapping interlevel theories also allows theories and explanations to be elaborated in a number of ways, and agrees with much of Kitcher's explanatory extension approach, although Schaffner and Kitcher and Culp continue to disagree on how to characterize theories in molecular biology (Schaffner 1993a).

One further aspect of Culp and Kitcher's characterization of molecular biology deserves comment: namely, their emphasis on experiment. One of the most striking features of molecular biology is the prominence of experimental techniques (see Experiment). A vital aspect of the structure of molecular biology is the presence and exportation of sets of techniques to address a vast array of different biological problems. While philosophers of science have been traditionally concerned with theories, the ongoing study of sciences like molecular biology is fuelling the growing concern with experimentation, so much so that it now seems difficult to characterize molecular biology without discussing the central role of experimental techniques, such as X-ray diffraction, electrophoresis, or polymerase chain reactions (Zallen 1993).

Molina, Luis de (1535-1600)

A leading figure in sixteenth-century Iberian scholasticism, Molina was one of the most controversial thinkers in the history of Catholic thought. In keeping with the strongly libertarian account of human free choice that marked the early Jesuit theologians, Molina held that God's causal influence on free human acts does not by its intrinsic nature uniquely determine what those acts will be or whether they will be good or evil. Because of this, Molina asserted against his Dominican rivals that God's comprehensive providential plan for the created world and infallible foreknowledge of future contingents do not derive just from the combination of his antecedent 'natural' knowledge of metaphysically necessary truths and his 'free' knowledge of the causal influence - both natural (general concurrence) and supernatural (grace) - by which he wills to cooperate with free human acts. Rather, in addition to God's natural knowledge, Molina posited a distinct kind of antecedent divine knowledge, dubbed 'middle knowledge', by which God knows pre-volitionally, that is, prior to any free decree of his own will regarding contingent beings, how any possible rational creature would in fact freely choose to act in any possible circumstances in which it had the power to act freely. And on this basis Molina proceeded to forge his controversial reconciliation of free choice with the Catholic doctrines of grace, divine foreknowledge, providence and predestination.

In addition to his work in dogmatic theology, Molina was also an accomplished moral and political philosopher who wrote extensive and empirically well-informed tracts on political authority, slavery, war and economics.

1 Life and writings

Luis de Molina was a leading figure in the remarkable sixteenth-century revival of scholasticism on the Iberian peninsula that also produced the likes of Pedro da Fonseca, Domingo de Soto, Domingo Báñez and Francisco Suárez. After entering the Jesuit noviciate in 1553, Molina studied philosophy and theology for ten years at Coimbra and Évora in Portugal, and then taught at these same colleges until retiring in 1583 to devote himself to writing. He spent the next sixteen years in Évora, Lisbon and Cuenca, before being summoned just before his death to teach moral theology in Madrid.

The most famous and controversial of Molina's three published works was the *Liberi arbitrii cum gratiae donis, divina praescientia, providentia, praedestinatione et reprobatione concordia (A Reconciliation of Free Choice with the Gifts of Grace, Divine Foreknowledge, Providence, Predestination and Reprobation)* (first published in 1588). Popularly known simply as the *Concordia*, this work was in large part extracted from the *Commentaria in primam divi Thomae partem (Commentaries on the First Part of Aquinas' Summa theologiae)*, subsequently published at Cuenca in 1592. Molina also wrote a five-volume work on political philosophy, *De Justitia et Jure (On Justice and Law)*, the first complete edition of which appeared only posthumously. Although there are also modern editions of a few unpublished pieces, most of Molina's shorter tracts and commentaries survive only in manuscript.

The publication of the first edition of the *Concordia* ignited a fierce controversy about grace and human freedom that had already been smouldering for two decades between the youthful Society of Jesus (founded in 1540) and its theological opponents. At Louvain, the Jesuit Leonard Lessius had been assailed by the followers of Michael Baius for harbouring views on grace and freedom allegedly contrary to those of St Augustine. In Spain and Portugal, the Jesuits were accused of doctrinal novelty by theologians of the more established religious orders, especially the Dominicans, led by the redoubtable Báñez.

When the dispute began to jeopardize civil as well as ecclesiastical harmony, political and religious leaders in Iberia implored the Vatican to intervene. In 1597 Pope Clement VIII established the *Congregatio de Auxiliis* (Commission on Grace) in Rome, thus initiating a ten-year period of intense investigation - including eighty-five hearings and forty-seven debates - that rendered the *Concordia* one of the most carefully scrutinized books in Western intellectual history. At first, things did not go well for the Jesuits; Molina died in Madrid amid rumours that he was being burned in effigy in Rome. However, due to the efforts of Cardinals Robert Bellarmine and Jacques du Perron, Molina's views emerged unscathed in the end. In 1607 Pope Paul V issued a decree allowing both parties to defend their own positions but enjoining them not to call one another's views heretical.

2 Grace and freedom

Both sides of the dispute over grace and freedom agree that in addition to creating and conserving contingent beings, God acts as an immediate efficient cause of all the effects produced by created or secondary causes, including acts of free choice (see Grace; Free will).

First, God acts as an immediate 'general' or 'universal' cause of all the natural effects produced through the powers rooted in the essences of natural substances. This immediate causal contribution is called God's general concurrence (*concursus generalis*) because even though in any given case the effect proceeds as a whole from both God and the relevant secondary causes, the fact that the effect is of one species rather than another is primarily traceable not to God's concurrence but to the natures and causal contributions of the created agents, which for this reason are called 'particular causes'. So, for instance, when a gas flame makes a pot of water boil, the fact that the effect is the boiling of water rather than, say, the blossoming of a flower is traceable primarily not to God's causal contribution, but rather to the specific natures and causal contributions of the secondary causes (gas, water, and so on). Likewise, any defectiveness in the effect is traced back causally to a defect or impediment within the order of secondary causes rather than to God's causal contribution, which is always, within its own order, causally sufficient (in the sense of 'enough') for its intended effect, even when that effect is not produced. When the intended effect is produced, God's concurrence is said to be 'efficacious' with respect to it; when it is not produced, God's concurrence is said to be 'merely sufficient' with respect to it. If a defective effect is instead produced, its defectiveness is something that God merely permits rather than intends.

This account applies straightforwardly to morally good and evil acts emanating from the power of free choice that rational creatures are endowed with by nature. No such act can occur without God's general concurrence, and in causally contributing to it God intends that the act be morally upright rather than sinful. None the less, because of defects in the free agents with whom God cooperates, his general concurrence is often merely sufficient - and thus inefficacious - with respect to the morally good act he intends. So even though God must concur causally in order for even a sinful act to be elicited, none the less, the act's defectiveness is traced back to the free created agent rather than to God, who permits the defect without intending it (see Sin). By contrast, when a morally good act is freely elicited, God's concurrence is efficacious with respect to it.

Second, God also cooperates with free human acts by means of the particular causal influence of supernatural grace, merited for the human race by the salvific death and resurrection of Jesus Christ. By this grace, God empowers and prompts human beings to elicit free acts of will that are supernaturally salvific, and he cooperates as a simultaneous cause in the very effecting of these acts. By eliciting such free acts of faith, hope, charity and the other infused virtues, human agents are able to attain and foster that intimate friendship with God which in its fullness constitutes their highest fulfilment as rational beings. Still, in so far as grace operates prior to the consent of human free choice, it can be freely resisted; and when it is resisted, it is said to be inefficacious, or merely sufficient, with respect to the salvific act God intends (see Salvation §4).

All this is accepted by both Molina and his Báñezian opponents (see Báñez, D.). Their dispute has to do with the 'intrinsic' character of God's simultaneous causal cooperation with free human acts. Regarding the natural order, Báñezians insist that there is an intrinsic ontological difference between efficacious and merely sufficient concurrence, so that of itself efficacious concurrence necessarily attains its intended effect, whereas of itself merely sufficient concurrence necessarily fails to attain its intended effect. So God grants intrinsically efficacious concurrence when and only when the human agent freely elicits the morally good act that God intends; and God grants intrinsically merely sufficient concurrence when and only when the human agent freely fails to elicit the morally good act that God intends. An immediate consequence is that God infallibly foreknows whether or not a human agent will freely elicit a morally good act at a given time, simply by virtue of knowing whether or not he himself will grant intrinsically efficacious concurrence with respect to that act.

The Báñezians hold a parallel position concerning the grace by which God operates to elicit supernaturally salvific acts. God grants intrinsically efficacious grace when and only when the human agent elicits the supernaturally salvific act God intends; and God grants intrinsically merely sufficient grace when and only when the human agent resists and thus fails to elicit the supernaturally salvific act that God intends.

Molina argues that this doctrine is incompatible with human freedom and falls into the strict determinism

advocated by the Lutherans and Calvinists. For even though the Báñezians, like Molina, insist that a free act of will cannot result by natural necessity from antecedently acting causes, they none the less assert that an act of will can be free even if God has predetermined to cooperate with it contemporaneously by a concurrence or grace that is intrinsically efficacious (or inefficacious). This Molina denies: ‘That agent is called free who, with all the prerequisites for acting having been posited, is able to act and able not to act, or is able to do one thing in such a way that he is also able to do some contrary thing’ (*Concordia*: 14). Numbered among these prerequisites is God’s fixed intention to confer his general concurrence and grace. So if God has decided to confer only intrinsically efficacious (or intrinsically inefficacious) grace or concurrence in a given situation, the created agent’s freedom is destroyed.

Molina’s alternative thesis is that God’s grace and general concurrence are intrinsically neither efficacious nor inefficacious. Rather, they are intrinsically ‘neutral’ and are rendered efficacious or inefficacious ‘extrinsically’ by the human agent’s free consent or lack thereof. Báñezians retort that this position savours of Pelagianism and violates the Catholic doctrine that God is the primary source of morally good and supernaturally salvific acts (see Pelagianism).

3 Providence and middle knowledge

Molina’s views about grace and freedom seem at first glance to jeopardize the Catholic tenets that God is perfectly provident and has infallible and comprehensive knowledge of future contingents.

According to the traditional doctrine of divine providence (see Providence §1), God freely and knowingly plans, orders and provides for all the effects that constitute the created universe with its entire history, and he executes his chosen plan by playing an active causal role that ensures its exact realization (see Providence). Since God is the perfect craftsman, not even trivial details escape his providential decrees. Whatever occurs is specifically decreed by God; more precisely, each effect produced in the created universe is either specifically and knowingly intended by him or, in concession to the defectiveness of creatures, specifically and knowingly permitted by him. Divine providence thus has both a cognitive and a volitional aspect. By his pre-volitional knowledge God infallibly knows which effects would result, directly or indirectly, from any causal contribution he might choose to make to the created sphere. By his free will God chooses one from among the infinity of total sequences of created effects that are within his power to bring about and, concomitantly, wills to make a causal contribution that he knows with certainty will result in his chosen plan’s being effected down to the last detail (see Omnipotence; Omniscience).

This much is accepted by both Molina and the Báñezians. They further agree that it is because he is perfectly provident that God has comprehensive foreknowledge of what will occur in the created world. That is, God’s speculative post-volitional knowledge of the created world - his so-called ‘free knowledge’ or ‘knowledge of vision’ - derives wholly from his pre-volitional knowledge and his knowledge of what he himself has willed to do. Unlike human knowers, God need not be acted upon by outside causes in order for his cognitive potentialities to be fully actualized; he does not have to, as it were, look outside himself in order to find out what his creative act has wrought. Rather, he knows ‘in himself’ what will happen precisely because he knows just what causal role he has freely chosen to play within the created order and just what will result given this causal contribution. In short, no contingent truth grasped by the knowledge of vision can be true prior to God’s specifically intending or permitting it to be true or to his specifically willing to make the appropriate causal contribution towards its truth.

Molina’s problem can now be stated succinctly. As noted above, he affirms against the Báñezians that God’s cooperating grace and general concurrence are intrinsically neither efficacious nor inefficacious. So if God has only his antecedent ‘natural knowledge’ of metaphysically necessary truths plus knowledge of his own total causal contribution to the created world, he cannot specifically provide for or know any actual or ‘absolute’ future contingents. His natural knowledge tells him only what each free secondary cause would be able to do, not what it would in fact do, in any possible situation in which it could act; and if his grace and general concurrence are intrinsically neutral, then his own causal contribution to the contingent effects of secondary causes cannot uniquely determine what those effects will be. How, then, can God be perfectly provident and have comprehensive knowledge of future contingents?

Molina replies that since there is genuine freedom and indeterminism in the created world, God can be perfectly

provident in the way demanded by orthodoxy only if his pre-volitional knowledge includes comprehensive knowledge of which effects would in fact result from causal chains involving free or indeterministic created causes. That is, God must have infallible and comprehensive pre-volitional knowledge of ‘conditional future contingents’ or *futuribilia* - metaphysically contingent propositions specifying how any possible indeterministic created cause would in fact act in any set of circumstances it might find itself in. Since this knowledge is of metaphysically contingent truths, it is not part of God’s natural knowledge; since it is pre-volitional, it is not part of God’s free knowledge. It stands ‘midway’ between natural knowledge and free knowledge - hence its title, ‘middle knowledge’ (*scientia media*).

According to Molina, then, the basis for God’s providence and his foreknowledge of absolute future contingents is threefold: (1) his pre-volitional natural knowledge of metaphysically necessary truths, (2) his pre-volitional middle knowledge of *futuribilia*, and (3) his post-volitional knowledge of the total causal contribution he himself wills to make to the created world. By (1) he knows which spatio-temporal arrangements of secondary causes are possible and which contingent effects might possibly emanate from any such arrangement. By (2) he knows which contingent effects would in fact emanate from any such arrangement. By (3) he knows which secondary causes he wills to create and precisely how he wills to cooperate with them via his intrinsically neutral cooperating grace and general concurrence. So given God’s pre-volitional natural knowledge and middle knowledge, he is able to choose a comprehensive providential plan; and given further his post-volitional knowledge of what his own causal contribution to the created world will be, he has free knowledge of all absolute future contingents.

The Bañezians counter by denying that any metaphysically contingent propositions, including any *futuribilia*, can be true prior to God’s freely making them true by his predetermining decree. This dissatisfaction with middle knowledge provides another reason for Bañezians to reject Molina’s strongly libertarian account of freedom, which engendered the need for middle knowledge in the first place. (Interestingly, by way of contrast, the main opponents of middle knowledge in twentieth-century analytic philosophy of religion retain Molina’s account of freedom and reject instead the traditional doctrines of divine providence and foreknowledge.)

4 Political philosophy

Molina holds a ‘translation’ account of political authority (see Political philosophy, history of). Unlike the ecclesiastical authority of the pope, which is bestowed immediately by God on the person designated by the ecclesiastical community, the governing authority of the political ruler is bestowed immediately by a community which has established itself as a commonwealth and in which political authority resides by natural law. Hence, unlike the ecclesiastical community, the political commonwealth not only designates its rulers but also legitimately limits the power it transfers to them and restricts their use of that power. Because of this, the individual members of the commonwealth can, under certain extreme circumstances, legitimately resist and defend themselves against tyrannical rulers.

Molina also addresses at length a wide variety of moral questions regarding war, slavery and economic matters such as taxation, free markets, monetary policy and price regulation. Given his historical circumstances, Molina’s ruminations about slavery are especially interesting. Like his Aristotelian predecessors, he believes that slavery is morally justifiable under certain limited circumstances. For example, those lawfully condemned to death may legitimately have their death sentences commuted to perpetual servitude; enemy populations conquered in a just war may legitimately be enslaved in restitution for damages to the victors; and free and willing adults may legitimately sell themselves into slavery. None the less, Molina’s many conversations in Lisbon with the captains of slave ships led him to conclude that the African slave trade as it was actually being carried out by the Portuguese was ‘unjust and wicked’ and that those who engaged in it, both sellers and buyers, were almost surely ‘in a state of eternal damnation’ (see Slavery).

Molinism

Molinism, named after Luis de Molina, is a theological system for reconciling human freedom with God's grace and providence. Presupposing a strongly libertarian account of freedom, Molinists assert against their rivals that the grace whereby God cooperates with supernaturally salvific acts is not intrinsically efficacious. To preserve divine providence and foreknowledge, they then posit 'middle knowledge', through which God knows, prior to his own free decrees, how any possible rational agent would freely act in any possible situation. Beyond this, they differ among themselves regarding the ground for middle knowledge and the doctrines of efficacious grace and predestination.

Molinism is an influential system within Catholic theology for reconciling human free choice with God's grace, providence, foreknowledge and predestination. Originating within the Society of Jesus (the Jesuits) in the late sixteenth and early seventeenth centuries, it encountered stiff opposition from Báñezian Thomists (see Báñez, D.) and from the self-styled Augustinian disciples of Michael Baius and Cornelius Jansen.

Molinism's three distinguishing marks are a strongly libertarian account of human freedom (see Freedom and liberty §1); the consequent conviction that the grace whereby God cooperates with supernaturally salvific free acts is not intrinsically efficacious (see Grace); and the postulation of divine middle knowledge (*scientia media*), by which God knows, before any of his free decrees regarding creatures, how any possible rational being would freely act in any possible situation (see Molina, L. de §§2-3; Omniscience).

Beyond this, Molinists disagree about three important issues. The first is the question of how God knows the 'conditional future contingents' or *futuribilia* that constitute the objects of middle knowledge. Molinists cannot accept the Báñezian claim that God knows *futuribilia* by virtue of his freely decreeing their truth, since according to Molinism *futuribilia* have their truth prior to any free divine decree. Nor can Molinists claim that God knows *futuribilia* simply by virtue of comprehending all possible creatures, if 'comprehending' a creature means just understanding all the metaphysical possibilities involving it. For such comprehension is insufficient for knowing how a possible creature would freely act - as opposed to how it could act - in any possible situation.

Molina himself claims that because God's cognitive power infinitely surpasses the natures of creatures, God is able to know those natures 'in a more eminent way than that in which they are knowable in themselves' (*Concordia*: 343). So God not only comprehends possible creatures but also 'super-comprehends' them, as later Molinists put it, and in this way knows *futuribilia* involving them. One corollary, explicitly defended by Molina, is that God does not know *futuribilia* concerning his own free decrees, since his cognitive power does not infinitely surpass his own nature.

Other Molinists retort that no amount of insight into the natures of possible creatures can yield infallible knowledge of *futuribilia*, since such natures are exhausted by their metaphysical possibilities and do not include *futuribilia*. Instead, God has direct knowledge of *futuribilia*, unmediated by his knowledge of natures, and this is simply because the *futuribilia* are true and hence intelligible to an infinite intellect. From this viewpoint there is no reason why God should not know *futuribilia* concerning his own free decrees - a result Molina takes to be incompatible with God's freedom.

The second dispute concerns the reason for the efficaciousness of the grace whereby God cooperates with supernaturally salvific acts of free choice. Suppose that in circumstances *C*, influenced by grace *G*, Peter freely elicits salvific act *A*. All Molinists agree that God places Peter in *C* with *G* knowing full well that Peter will freely elicit *A*; and they also agree that *G* is not intrinsically efficacious and hence does not causally predetermine *A*. However, there is strong disagreement about whether or not it is Peter's free consent alone that 'extrinsically' renders *G* efficacious in *C* with respect to *A*.

One possibility is that God first resolves absolutely that Peter should freely elicit *A* in *C* and then, as it were, consults his middle knowledge to see just which particular graces would, if bestowed on Peter in *C*, obtain his free consent and thus issue in *A*. It follows that, given his antecedent resolution, God would have conferred some grace other than *G* if he had known by his middle knowledge that *G* would turn out to be 'merely sufficient' with respect to *A*, that is, that Peter would not freely consent to *G* in *C*. So *G* is rendered efficacious not only by Peter's free

consent but also, and indeed more importantly, by God's antecedent predetermination to confer a 'congruous' grace that will guarantee Peter's acting well in *C*. This model, which brings Molinism more into line with Báñezianism, is known as Congruism and was worked out in detail by Robert Bellarmine and Francisco Suárez (§1). In 1613 Congruism was mandated for all Jesuit theologians by the Father General Claude Aquiviva.

Another possible model, which seems to be Molina's own, is that God simply wills to put Peter into *C* with *G*, knowing that Peter will freely elicit *A* but not having absolutely resolved beforehand that Peter should freely elicit *A*. This model does not entail that if God had known that Peter would act badly in *C* with *G*, he would have conferred some grace other than *G* in order to guarantee *A*. Accordingly, it is Peter's free consent alone that renders *G* efficacious.

An analogous dispute arises over predestination, where the question concerns not one or another of Peter's acts, but his eternal salvation. Some Molinists, including Bellarmine and Suárez, agree with the Bañezians that God antecedently elects certain people to eternal glory and only then consults his middle knowledge to discover which graces will guarantee their salvation. Thus, in Peter's case, God would have chosen different graces if those he actually chose had been foreknown to be merely sufficient and not efficacious for Peter's salvation. Other Molinists, including Molina himself, vigorously reject any such antecedent absolute election of Peter to salvation. They insist instead that God simply chooses to create a world in which he infallibly foresees Peter's good use of the supernatural graces afforded him, and only then does he accept Peter among the elect in light of his free consent to those graces.

Molyneux problem

The origin of what is known as the Molyneux problem lies in the following question posed by William Molyneux to John Locke: if a man born blind, and able to distinguish by touch between a cube and a globe, were made to see, could he now tell by sight which was the cube and which the globe, before he touched them? The problem raises fundamental issues in epistemology and the philosophy of mind, and was widely discussed after Locke included it in the second edition of his Essay concerning Human Understanding.

1 The origin of the problem

William Molyneux (1656-98) was a leading Irish scientist whose wife became blind shortly after marriage. His consequent interest in vision gave rise to *Dioptrica Nova (New optics)* (1692), a treatise on optics which also touches on the psychology of vision. The main problems for seventeenth-century theories of vision arose from the apparent conflict between physical theories about light and the phenomenology of perception. For example, optics demonstrates the inversion of the retinal image, but we perceive the object the right way up. Moreover, the retinal image is flat, but we perceive distance and depth. In response to these problems, Descartes postulated an innate judgment by which the soul corrects the inverted retinal image, and he ascribed the perception of distance partly to 'natural geometry'. We unconsciously calculate the distance of objects from the angles of the incoming light rays and the distance between our eyes.

Molyneux's treatment of the perception of distance or depth falls into two parts. Perception of the distance of far-off objects, he agrees, involves an act of judgment: 'For Distance of itself, is not to be perceived, for 'tis a Line (or a Length) presented to the Eye with its End towards us, which must therefore be only a Point, and that is Invisible' (Molyneux 1692: 113). But perception of near-distance is assigned, somewhat vaguely, to unconscious natural capacities. Near objects are perceived 'by the turn of the eyes, or by the angle of the optic axes' explanations going back, via Descartes and Kepler, to medieval theories of perception.

While writing *Dioptrica Nova* Molyneux read the French abstract, published in 1688, of Locke's *Essay concerning Human Understanding*, and sent the author the following problem:

> A Man, being born blind, and having a Globe and a Cube, nigh of the same bigness, committed into his Hands, and being taught or Told, which is Called the Globe, and which the Cube, so as easily to distinguish them by his Touch or Feeling; Then both being taken from Him, and Laid on a Table, let us suppose his Sight Restored to Him; Whether he Could, by his sight, and before he touch them, know which is the Globe and which the Cube? Or Whether he could know by his sight, before he stretched out his Hand, whether he Could not Reach them, tho they were Removed 20 or 1000 feet from him.
>
> (Letter to Locke, 7 July 1688)

Despite receiving no reply, Molyneux dedicated his book to the 'incomparable Mr. Locke' and sent him a copy. In the ensuing correspondence Molyneux again posed the problem. This time Locke judged it an 'ingenious problem', including it in the second edition of his *Essay* (1694).

2 Philosophical responses

Philosophers' answers to Molyneux's problem and their conception of its significance reflect their general epistemology. Both Locke's empiricism and his requirement that any idea is such as the subject perceives it to be rule out the possibility of the sort of innately guided, unconscious reasoning postulated by Descartes. The perception of distance is therefore an acquired ability and the answer to Molyneux's question is negative. This reply may seem inconsistent with Locke's doctrine that ideas of primary qualities, such as shape or motion, resemble their causes: visual and tactual ideas of such qualities have common causes, which implies that they resemble each other. However, Locke saw Molyneux's problem simply as showing that 'the Ideas we receive by sensation are often in grown People alter'd by the Judgement, without our taking notice of it' (1689: ch. II, §8). The ideas we receive by sight are allegedly only two-dimensional patterns of light and colour. In order to be able to recognize a three-dimensional shape or body in these patterns, we need to know how to correlate them with information provided by touch. The visual idea is like a word which induces in a hearer the associated idea, but is

itself hardly noticed (see Locke, J. §§2, 4).

Leibniz (1765) accepted that the connection between the visual and the tactual sensations is not innate. However, if the blind person has been given the information that a cube and a globe lie in front of him, they can work out which is which from the geometric features the visual and the tactual ideas share. In the cube there are eight points distinguished from all the others, whereas in the globe there are none. This shows, Leibniz concludes, how important it is to distinguish sensory images from ‘exact ideas constituted by definitions’ (see Leibniz, G.W. §8). Another of Locke’s contemporaries, Edward Synge (1695), insisted on a somewhat similar distinction between image and sensation on the one hand, and idea and perception on the other. He argued that, although the images acquired by sight and touch are different, the ideas are identical. In recognizing a cube by sight and by touch only one conceptual ability is involved.

Berkeley took a contrary view, rejecting Locke’s account of primary qualities and arguing that ideas of sight and touch are radically heterogeneous, connected only by contingent correlations known through sense experience. His reasons for endorsing the negative answer to the problem, and for his enthusiastic development of the analogy with language, are thus far more radical than Locke’s (see Berkeley, G. §4).

The Molyneux problem was widely discussed in the eighteenth and nineteenth centuries (indeed Ernst Cassirer has claimed that it was the fundamental question for both continental and Anglo-saxon epistemology and psychology in the eighteenth century). Among the contributors were Condillac and Diderot whose *Lettre sur les aveugles (Letter on the blind)* contains a fascinating description of the difference between the ‘life-world’ of the blind and that of the sighted. Various attempts have been made to answer the question empirically, the first being ‘Cheselden’s case’, named after the surgeon who, in 1728, reported an operation performed on a boy with congenital cataract. Since it took some time for the boy to perceive and recognize objects by sight, Cheselden’s case was supposed to confirm the negative reply. Yet even Leibniz had foreseen that the subject might be ‘dazzled and confused by the strangeness’. In any case, since blindness is a symptom resulting from different diseases of the eyes and along the optical tract, it is difficult to assess what bearing empirical data have on the Molyneux problem.

On any interpretation, the Molyneux problem raises the issue of the relation between the perceptual representation of space attributable to the blind and that made available by sight. Berkeley’s radical assertion of heterogeneity assigned primary spatial experience to touch, treating visual ideas as mere signs of impending or available tactual ideas. Conversely, it might be questioned whether the blind possess genuine spatial concepts, on the grounds that they only have successions of tactual experiences. Possession of spatial concepts, however, involves thought of distinct objects existing not in succession but simultaneously. Yet both these views ignore the fact that there is only one behavioural space for a subject to move around in. Simply to act, a subject - whether blind or sighted - must have experience of egocentric space involving an ability to locate what is perceived, however perceived, in relation to their body. If that is correct, the chief question remaining is how readily a blind subject, made to see, is able to generalize spatial concepts to visual experiences.

Momentariness, Buddhist doctrine of

*The object of the Buddhist doctrine of momentariness is not the nature of time, but existence within time. Rather than atomizing time into moments, it atomizes phenomena temporally by dissecting them into a succession of discrete momentary entities. Its fundamental proposition is that everything passes out of existence as soon as it has originated and in this sense is momentary. As an entity vanishes, it gives rise to a new entity of almost the same nature which originates immediately afterwards. Thus, there is an uninterrupted flow of causally connected momentary entities of nearly the same nature, the so-called continuum (*santāna*). These entities succeed each other so fast that the process cannot be discerned by ordinary perception. Because earlier and later entities within one continuum are almost exactly alike, we come to conceive of something as a temporally extended entity even though the fact that it is in truth nothing but a series of causally connected momentary entities. According to this doctrine, the world (including the sentient beings inhabiting it) is at every moment distinct from the world in the previous or next moment. It is, however, linked to the past and future by the law of causality in so far as a phenomenon usually engenders a phenomenon of its kind when it perishes, so that the world originating in the next moment reflects the world in the preceding moment.*

At the root of Buddhism lies the (never questioned) conviction that everything that has originated is bound to perish and is therefore, with the exception of factors conducive to enlightenment, ultimately a source of frustration. There is no surviving textual material that documents how this law of impermanence came to be radicalized in terms of momentariness. It seems that by the fourth century the doctrine of momentariness had already assumed its final form. Characteristically, the debate became more and more dominated by epistemological questions, while the metaphysical aspect faded into the background.

1 Exposition

The doctrine of momentariness entails that entities are too shortlived to undergo change. Thus, if an entity has always engendered a new entity of exactly the same kind and with exactly the same properties, the worlds arising at every moment anew would be identical, so that there could be no evolution. This, however, is not the case because the process of reproduction of a given entity may be manipulated by outside factors in such a way that the newly created entity differs qualitatively from the preceding entity. If exposed to fire, for instance, a wood entity does not give rise to an identical wood entity when it perishes, but to a wood entity which bears the mark of impairment by fire and so is slightly charred. (According to later parlance, the wood as the main cause forms, together with the fire as a subsidiary cause, a causal complex which produces the slightly charred wood entity.) Thus, change is not constituted by the transmutation of persisting entities, but by the qualitative difference between earlier and later entities within a series.

Not only the transformation of series but also their cessation (that is, what is ordinarily conceived of as the utter annihilation of temporally extended objects), is caused by an external agent, which affects the process of reproduction of the object exposed to it in such a way that this process comes to a complete standstill. Hence, in the case of murder, the victim dies because the murderer affects the final moment of the breath of life (*prāṇa*), that is, the vital principle accounting for the body's animation, in such a way that it fails to reproduce itself. Since the final moment (like all preceding ones) passes out of existence automatically, murder is, microscopically speaking, not destruction but the interception of the process of reproduction. In this way the teaching that all entities pass out of existence spontaneously without depending for this upon any external cause is reconciled with the observation on a macroscopic level that wood is burnt by fire, or that one dies when knifed by a murderer.

Independently of the doctrine of momentariness, the Buddhists, like many other Indian schools, also dissected everything spatially into atoms (see Matter, Indian conceptions of). Thus, in the final analysis, the world is made up of momentary atoms, which by their spatial arrangement and by their concatenation with earlier and later atoms of the same kind, give rise to the illusion of persisting compact things. This analysis of existence can be illustrated by referring, anachronistically, to cinematography. Just as the rapid projection of distinct pictures evokes the illusion of continuous action on the screen, so the fast succession of distinct momentary entities gives rise to the erroneous impression that the world around us (and we ourselves) exist continuously without undergoing destruction and being recreated every moment. Similarly, as the change of events on the screen is caused by the

qualitative difference between earlier and later pictures on the film reel, so the change in the world is brought about by the qualitative difference between earlier and later entities. Moreover, as people vanish from the screen because they are not featured in the subsequent frame, so things cease to exist because they stop reproducing themselves. Finally, just as each projected picture only consists of differently shaded points, which by their specific arrangement give rise to the perception of composite shapes, so the world around us consists of nothing but distinct atoms which are arranged in such a way that they convey the impression of compact bodies.

2 Relevance

The Buddhist doctrine of momentariness does not challenge our experiences of macroscopic events as such, but only our interpretation of these events on a microscopic level. The claim that macroscopic objects are constituted by a succession of distinct momentary units only affects the intuitive conception of these objects as self-identical units (think of the notion of an uninterrupted line in contrast to one made up of distinct but contiguous points), but it does not affect the question of how these macroscopic objects behave, whatever their analysis on a microscopic level.

The doctrine of momentariness was not viewed as a purely metaphysical theory without practical relevance. On the contrary, the contemplation of the constant rise and fall of phenomena was employed to induce a particularly poignant experience of their impermanence, thus revealing the unsatisfactory nature of all existence. Moreover, in a Mahāyāna context this contemplation served as a tool for undermining (but not negating) the substantial existence of phenomena. However, since only advanced yogins seem to have been able to perceive momentariness directly, the soteriological significance of this doctrine remains very limited. This explains why it only played a marginal role in the wider context of Buddhist spirituality.

3 Development

The doctrine of momentariness is postcanonic and may have originated in the first century. It is for the first time presupposed in the *Vibhāṣa* (both in the Chinese translation by Xuanzang (Hsüan-tsang) and by Buddhavarman) of the Sarvāstivādins, one of the major Hīnayāna schools of Buddhism. In this scholastic compendium, the better part of which was probably compiled in the second century, the momentariness of all phenomena is not treated as a topic in its own right, but is frequently taken for granted when dealing with other issues.

Doxographical reports and other evidence confirm the impression that it was in the milieu of the Sarvāstivādins that all phenomena, more precisely all conditioned entities (*saṃskṛta*, *saṃskāra*), came to be looked upon as momentary. (The Sarvāstivādins treated space and two forms of suppression of certain factors as unconditioned entities (*asaṃskṛta*) which have never been created and, hence, are not subject to the law of impermanence, hence the specification at this point that momentariness only applies to conditioned entities and not to all phenomena.) Although the Sarvāstivādins reduced the duration of all phenomena to a moment, they still conceived of their existence much in the same way as they had done before the introduction of the doctrine, insisting that even within one moment they first originate, then persist and decay and finally perish. This treatment violated the common conception of the moment (*kṣaṇa*) as the shortest conceivable unit of time and consequently was rejected by the Dārṣṭamacr;(ntikas and Sautrāntikas, who are closely related to the Sarvāstivādins and may have evolved from them. These two schools argued that contradictory events cannot take place within one moment. From this they concluded that all things perish as soon as they have originated. Since destruction was conceived of as the spontaneous cessation of existence and not as a time-consuming process, the existence of entities was reduced to mere acts of origination, flashes into existence.

With this radicalization of the instantaneous nature of existence, the doctrine of momentariness assumed its final form. Such a form was adopted by the Yogācāras, one of the two main Indian schools of Mahāyāna Buddhism, and came to be known by other Buddhists and non-Buddhists. The Yogācāras with a Mahāyāna orientation, however, only accepted the doctrine of momentariness as valid on the level of relative truth. In so far as the doctrine affirms the existence of discrete entities (although they are reduced to mere point instants), it is characteristic of the realism of Hīnayāna Buddhism and at odds with their Mahāyāna stance that all phenomenal entities are ultimately, on the level of highest truth, unreal (see Buddhism, Yogācāra school of).

4 Doctrinal background

The surviving sources do not record how the doctrine of momentariness originated. Hence the reconstruction of this process has to be hypothetical. The anti-substantialist tendency characteristic of Buddhism denies that entities have a substantial core beyond the sum of their properties and thus equates the properties with the entities themselves. Hence, phenomena in Buddhism are called *dharmas*, a term with a wide range of meanings which is used in this context because it may stand for ‘property’ and ‘quality’. Since change was viewed as the replacement of one quality for another, the identification of property and entity led to the position that any qualitative change implies numeric difference, that is, the substitution of one entity for another. When Buddhists applied this understanding of change to their analysis of ageing they were bold enough to conclude that the ageing body must at every moment vanish to be replaced by a new, slightly modified body. As all things were conceived of as constantly changing, momentariness had to be attributed in this way not only to bodily matter but also to all other things. The conviction that everything is always changing (in as much as it is always subject to ageing) had resulted from the contemplation of the law of impermanence.

The discovery of the doctrine of momentariness in this way was possible because at a much earlier stage the momentariness of all mental entities had already been established in an apparently analogous way. This way was the denial of a permanent Self, a cardinal tenet of scholastic Buddhism which led to the conception of the mind as a flow of mental events conceived of as entities in their own right (see Buddhist concept of emptiness). Their momentariness was probably deduced from the speed with which mental events normally follow each other. The establishment of the doctrine of momentariness may have benefited from the testimony of yogins who are reported to have access to the direct experience of the incessant rise and fall of phenomena at every moment.

5 Proofs

Such a doctrine, fundamentally at odds with the appearance of the world, met great opposition. Initially, it was rejected by large sections of the Buddhist community, notably the Vātsīputrīyas and related schools. Later, when it had gained ground among Buddhists, it was fervently opposed by the Brahmanical schools as it contradicted their postulation of eternal entities of one sort or another (souls, atoms, primary matter, a supreme deity). This rejection made it necessary to defend the doctrine by argumentation.

The oldest transmitted proofs of momentariness are recorded in early Yogācāra sources. They are still primarily directed against other Buddhists and derive the momentariness of all phenomena in three different ways. First, it is presupposed that the mind is momentary - this stance is also shared by Buddhist opponents who do not accept the momentariness of matter - and on this basis it is concluded that matter, too, has to be momentary. This conclusion is based on the demonstration that mind and matter can only depend upon each other and interact as they do because they have the same duration. Second, by referring to ageing and similar processes it is proved that everything changes all the time and thus undergoes origination and destruction at every moment. This argument rests on the presupposition that any form of transformation implies the substitution of one entity for another. This proof from change reflects the presumable doctrinal background underlying the formation of the doctrine of momentariness. Third, it is argued that everything has to perish as soon as it has originated because, otherwise it would persist eternally. This would be at odds with the law of impermanence. The argument rests on the presupposition that destruction cannot be brought about from without and that it is impossible for an entity to perish on its own account after it has persisted as this would require a change of nature. The latter presupposition reflects the view that self-identical entities cannot change.

Vasubandhu (fourth-fifth century) marks the gradual transition between the earlier phase when the debate was still confined to Buddhism and the later phase when it was carried out between Buddhists and non-Buddhists. Vasubandhu only adopted the third type of proof, deducing momentariness from the spontaneity of destruction. He developed this idea further with the argument that destruction cannot be caused since, as mere nonexistence, it does not qualify as an effect. Up to the time of Dharmakīrti (*c*.600-60) and to a lesser extent thereafter, this proof of momentariness, the so-called inference from perishability (*vināśitvānumāna*), dominated the controversy.

With Dharmakīrti, the doctrine entered a new phase. He developed a new type of proof, the so-called inference from existence (*sattvānumāna*), that derives the momentariness of all entities (without presupposing their impermanence) directly from the fact that they exist. On the basis of the premise that existence entails causal efficiency, Dharmakīrti demonstrates that all existing things have to be momentary as it is impossible for nonmomentary entities to function as efficient causes. This impossibility derives from the idea that, if the entities

already produce their effect in the first moment, they also have to produce it again and again at all subsequent moments of their existence. This is an absurd position as their nature then does not differ from their nature in the first moment; nor can they discharge their causal efficiency gradually. If they were not able to produce their effect completely from the beginning, neither should they be able to do so later as this would entail a change of nature. This argument is also based on the premise that one and the same entity cannot change its properties.

The inference from existence became more prominent than the inference from perishability, although it never superseded it completely. Its prominence can be explained partly by the logical peculiarity of this proof which gave rise to an epistemological debate about the correct form of a valid syllogism. Since momentariness is to be proved for everything, all entities are the subject of inference (*pakṣa*). Thus, the inference from existence fails to fulfil two of the three classical conditions (*trairūpya*) for a valid syllogism, namely a positive and negative exemplification of the logical nexus (*vyāpti*) between the reason (to be existent) and the argued property (to be momentary) outside the subject (see Inference, Indian theories of).

Among other responses, this problem led to the modification of the conditions of a syllogism in such a way that those *vyāptis* also became accepted as valid where the logical relation between reason and argued property is not induced from other cases. This solution was already developed by Dharmakīrti himself, however, it was neglected until the time of Ratnākaraśānti (eleventh century). He argued that in those syllogisms where the proving property is intrinsic to the subject (*svabhāvahetu*), the logical nexus is to be established by demonstrating that the proving property cannot inhere in a locus that is lacking the argued property.

Frequently, as a corollary of these proofs of momentariness, the Brahmanical arguments against this doctrine are refuted. The most prominent argument - that the recognition of phenomena disproves their contended momentariness - is invalidated by the contention that recognition is a mixture of perception and memory and does not therefore qualify as a valid means of knowledge (*pramāṇa*). The related argument, that the mind cannot be a mere stream of momentary mental entities because memory and the discernment of causal relationships presuppose an enduring subject, is rejected. It is so on the grounds that the knowledge of the past is, by the principle of causal concatenation, passed on from one mental entity to the next. Thus, it is transmitted down to the present moment in a way which we may compare to the transmission of historic data from generation to generation.

Over the centuries the debate on the doctrine of momentariness developed to such an extent that Ratnakīrti (eleventh century) felt the need to deal with the inference from perishability, the inference from existence and the refutation of the proof of duration each in a separate treatise.

Monboddo, Lord (James Burnett) (1714-99)

In speculating that orang-utans' vocal organs must have been designed for speech, Monboddo was convinced that these creatures were primitive humans who had not yet entered society. His chief contribution to the history of linguistics and anthropology turns upon two propositions: that language is not natural to man, and that close physical resemblance between species is evidence of biological relation.

By training as a jurist and through his writings as a linguist and anthropologist, Monboddo was one of the most learned figures in eighteenth-century Scotland. Appointed a law lord or judge on the Scottish Court of Session in 1767 (from which his title derives), he drew lifelong inspiration from the classicism of Thomas Blackwell, whose writings on Homer and Augustus had helped to convince him of the decline of modern man and the decadence of modern forms of speech by contrast with the heroism of the ancient Greeks and Romans and the poetic resonance of their languages. More hostile to the empiricist tendencies of contemporary British philosophy than any other predominantly secular writer of the Scottish Enlightenment, he sought to rescue the glorious achievements of ancient science, ethics and rhetoric in reformulating an essentially Aristotelian interpretation of the human faculties, published in six volumes from 1779 to 1799, entitled*Antient Methaphysics* (see Enlightenment, Scottish).

A similar enthusiasm for classicism over modernity is manifest in Monboddo's more influential work of roughly the same period, *Of the Origin and Progress of Language*, also published in six volumes between 1773 and 1792. In addition to commenting on the splendours of ancient Latin and Greek, this text discusses the nomenclature of a variety of exotic languages, including Huron, Carib, Eskimo and Tahitian, which Monboddo had learned through dictionaries and travellers' reports. His attempt to trace the natural history of languages as an expression of both the universal capacities of the human mind and the specific genealogies of diverse cultures drew Monboddo in the direction of the nascent sciences of etymology and historical linguistics along lines developed by Sir William Jones (1746-89), with whom he corresponded. But he was even more drawn to the anthropological linguistics sketched in the *Discours sur l'inégalité (Discourse on the Origin of Inequality)* (1755) of Jean-Jacques Rousseau, from which Monboddo adopted and developed two main propositions: first, that language must be cultivated and mastered in society and hence is not natural to man; and, second, that the 'orang-utan' (in the Enlightenment a generic term for all the great apes) is human, since the inarticulacy of this creature so similar to a human being is attributable to its not yet having had the opportunity to enter society and therein to exercise its larynx, pharynx and other organs of speech. Monboddo imagined that analogous physical traits characteristically signify homologous functions, so that unless Nature had been so uneconomical as to engage in redundant design, the apparently human vocal organs with which orang-utans are endowed must have been intended for speech. It is a wonder that some of our forebears invented language at all, he claimed, since language does not spring spontaneously from our lips as does sight from our eyes or hearing from our ears. In time, and with proper tuition, he concluded, as some primatological researchers still do today, orang-utans would bridge the putative gulf created by language between human nature in society and the conduct of apes outside it (see Animal language and thought).

Monism

'Monism' is a very broad term, applicable to any doctrine which maintains either that there is ultimately only one thing, or only one kind of thing; it has also been used of the view that there is only one set of true beliefs. In these senses it is opposed to the equally broad term 'pluralism'. But it is also often contrasted with 'dualism', since so much philosophical debate has focused on the question whether there are two different kinds of thing, mind and matter, or only one.

The ending '-ism' suggests a particular theory or school; but in the case of 'monism' this is somewhat misleading. Less misleading is to think of certain philosophies as monistic in respect of some central doctrine, realizing that which doctrine this is may differ widely from case to case. This approach gives the flexibility to see that a philosophy which is from one perspective a variety of monism may well be, in respect of some other central doctrine, not monistic at all. For instance, Spinoza took the view that there was and could be only one substance (see Substance). But he also held that this substance had infinitely many attributes, of which all but two (the mental and the physical) are unknown to us. There is nothing wrong with calling Spinoza a monist - provided it is said with an eye to a particular feature of his system.

With that warning in mind, we can say that the most common use of 'monism' is to describe philosophies which maintain that there is, ultimately, only one thing, and that 'the Many' are aspects of it or, to a more radical way of thinking, simply an illusion resulting from our mis-perception of the One. What they are not, for an ontological monist, is a collection of independent existences. Bertrand Russell once wrote that Hegel thought reality was like a tin of treacle, whereas he (Russell) thought it was like a heap of shot - the metaphor is even better if we keep the treacle in mind and forget the tin.

A spectacular early example of monism is found in the thought of Parmenides, who obscurely argued that reality could consist only of one thing, changeless and undifferentiated, and that the appearance of plurality was illusory (see Parmenides §7). In later antiquity, Plotinus influentially declared that everything emanated from another such changeless and undifferentiated entity, 'the One'. In the nineteenth century the view (associated in particular with F.H. Bradley) became widespread that relations between distinct entities cannot ultimately be real: for if two such entities are related by some relation *R*, there would be need of further relations to relate the relation *R* to each of them, and so on into infinite regress. Therefore there can only really be one thing, for if there were more they would have to be in some way related to each other. A similar argument occurs in Indian thought (see Monism, Indian §3). Those who are sceptical will suspect that it rests on the tacit and dubious assumption that a real relation would have to be a kind of thing, like the things it relates.

A very different group of doctrines is also often called 'monism': those doctrines which assert, not that there is only one thing, but that there is ultimately only *one kind* of thing, one basic stuff of which the many kinds we observe are variant forms. Tradition unreliably has it that Thales, the earliest Greek philosopher of whom we have record, taught that this basic substance was water; a little later Anaximenes held a similar view, but chose air as his elemental stuff. They were therefore monists in this second sense, as is anyone who believes that the variety of the world is really nothing more than different arrangements of atoms which are themselves identical (see Atomism, ancient).

One version of the 'one stuff or more?' debate has been especially prominent in modern philosophy: are there two kinds of substance - matter and mind - or only one, and, if so, which? Here the question is not 'are there one or more?' but 'are there one *or two*?', and when philosophers speak of monism as the alternative to dualism (without saying one or two *what?*) it is nearly always this issue that they are referring to. (A quite different use of the term 'dualism' is used in religious thought to refer to the view that the world is the work of two powers, one good and one bad - see Manicheism §§1, 4.) In modern times, Descartes is the classic exponent of mind-body dualism, though hardly its inventor - he was only giving precision and proof to the very old idea that as well as matter there are spirits or souls, and that the latter are very different in kind from the former. Ranged on the other side are various styles of monist. There is idealist monism, typified by Berkeley, which holds that there are only minds or spirits, and that material bodies are nothing but a way of speaking about mental states (see Phenomenalism); there is material monism, steadily more popular with the rise of the natural sciences, which views everything as

material, and reduces the supposedly mental to facts about matter (see Materialism in the philosophy of mind). And there is a doctrine associated in particular with the names of Mach, James and Russell, which sees the mental and the physical as different aspects of a single basic stuff that in itself is neither mental or physical (see Neutral monism).

Because of its very general meaning, ‘monism’ lends itself to a wide variety of uses easily understood from their context. Thus one may see ‘value-monism’ - meaning an ethical system which recognizes only one thing as having value in itself, for example happiness (see Utilitarianism). And one may speak of monism about truth, meaning that there is one unique set of truths - in opposition to pluralism, relativism and perspectivalism, according to which conflicting or incommensurable views may be equally true.

Monism, Indian

The prominent classical and modern Indian philosophy known as Advaita Vedānta, which insists on the single reality of Brahman (the Absolute), is often identified as Indian monism. But the monism of Advaita is only a portion, albeit central, of the Advaita view. Furthermore, a monism in theology (Brahman as God) is important to almost all expressions, classical and modern, of Indian theism.

The monism of Advaita is principally psychological. Nondual awareness is considered the true self; that is to say, in the self's native state, the object of awareness and awareness itself are identical. This kind of awareness is claimed to be presupposed by all dualistic consciousness. Moreover, it is said that only self-aware self-awareness itself cannot be revealed by experience to be illusory. And according to Advaita, a supreme mystical experience, popularly called liberation, does in fact, when it occurs, reveal self-awareness to be the sole reality. A dialectical Advaita adds the further contention that it is impossible to define and explain coherently diverse appearances. This contention is cashed out by long and intricate attacks on the pluralistic ontologies of rival schools, particularly Nyāya-Vaiśeṣika.

The monism of Indian theism centres on the reality of God, who is constrained by metaphysical law to create out of the single spiritual substance that God is. The world is commonly said to be God's body. Various ramifications of God's being in some way everything can be discerned in Indian theology.

1 The Advaita view of self

Advaita Vedānta is a scripturally derived philosophy centred on the proposition, first found in early Upaniṣads (800-300 BC), that Brahman - the Absolute, the supreme reality - and the self (*ātman*) are identical. The identity is understood as an objectless consciousness, as awareness nondualistically self-aware. Arguments in support of the view that nondual awareness is the sole reality are developed by classical and modern Advaitins, from Gauḍapāda (*c*.600 AD) and Śaōkara (*c*.700 AD), in hundreds of texts. Some of these are suggested in Upaniṣads.

Scripture - that is, Upaniṣadic passages - is the principal reason cited why, in the first place, awareness aware of nothing but itself should be considered a reality. A supreme mystical experience, deemed the goal of life, is said to be just such a state, and scripture is interpreted as teaching this. But that so-and-so reports such mystical experience is not cited, at least not commonly, in support of the view that such self-awareness occurs. Scripture is the testimony of the occurrence.

That nondual awareness is the only possible *self*-awareness is defended by a *reductio* argument. If a further awareness C_2, having C_1 as content, is required for self-awareness, then since there would be no awareness of C_2 without awareness C_3, *ad infinitum*, there could be no self-awareness, that is, unless the self is to be understood as limited to past awareness only. For self-awareness to be an immediate awareness, self-awareness has to be nondual. It is a further question how self-aware awareness accounts for our everyday sense of self and our commitment to the reality of self, a question of psychology that in particular a few late classical Advaitins struggle with. It is problematic, for example, how our native self-awareness, aware only of itself, accounts for our everyday sense of ourselves as a body. Moreover, self-awareness, as understood by Advaita, is said to be presupposed by all consciousness, but the precise connection - other than as an ongoing possibility of meditative self-absorption - is not clearly worked out. Nevertheless, the argument that self-awareness would be impossible without nondual awareness is forceful, it is said, for all who admit self-awareness, and forceful, so it is presumed by many Advaitin advocates, independently of the question of the precise nature of the tie to the everyday sense of self.

In support of awareness as self-illumining, the great Advaitin Śaōkara (often taken to be the very founder of Advaita) argues that no one says 'I am not.' This Advaita argument for self-illumination is often compared to Descartes' *Cogito*. As self-illumining, awareness blocks doubt: the doubt never occurs, 'Am I aware or not?' In this way an appeal is made to what is sometimes called pragmatic contradiction: there would be contradiction between essence and content were someone to have an awareness verbalizable as 'I am not aware.' (Compare a speaker saying 'I am not speaking.')

From self-illumination it is argued that an epistemic principle known as self-certification (*svaprāmāṇya*) is right

concerning all questions about awareness, since only an awareness itself has, so to say, access to itself. Awareness itself is the only consideration relevant to any question about awareness itself, its existence or its nature. Self-certification is thus grounded in self-illumination. And self-certification is key to further Advaita arguments.

2 Sublatability

The most commonly voiced argument in defence of the Advaita view of self-awareness as the single reality centres on a presumed sublatability of all indications of awareness other than self-awareness itself. Perceptual illusion shows that there is no worldly content of an experience that could not prove unreal. In contrast, (again) no one says, or could say (in good faith), 'I am not.' The self, unlike objects presented perceptually, all of which might not be, cannot, if presented, possibly not be. Self cannot be sublated. Perceptual illusion shows that anything else can be. The appearances of a rope as a snake, of mother-of-pearl as silver, and so on, show that the worldly content of experiences is not to be trusted. Only self-experience is sure (see Error and illusion, Indian conceptions of §1).

Thus awareness self-certifyingly illumines self-awareness but not anything else. External objects are not self-certifyingly illumined because any presentation of an external object is sublatable, whereas the self-illumination of awareness itself is nonsublatable. All awareness may be *prima facie* self-certifying, but only self-awareness is *ultima facie* self-certifying, for all content other than self-illumination is sublatable, negatable experientially.

Advaitins move from these Cartesian-like considerations to embrace a very strong criterion for ontic commitment. An absolute nonsublatability is the mark, they say, of the real, or existent, *sat*. That which is not sublatable by any manner or means is to be accepted as real. Only self-awareness meets the criterion. Self-awareness is the single reality.

There is another argument centring on a sublatability of a different sort, not the experiential sublatability of presentations other than self, but a propositional defeasibility. Brahman, the Absolute, with which in the Upaniṣads the self is declared to be identical, is presented in the Upaniṣads as also including everything (*sarvam idaṃ brahma*, 'All this is Brahman'). The scripturally conveyed cognition of Brahman is not the same as self-awareness aware only of itself, for the scripturally conveyed cognition of Brahman is verbal, conveyed linguistically. It is only self-awareness that cannot possibly be sublated experientially and thus it is only that awareness that indicates reality in the truest sense of the word. But (unfortunately) we do not live our lives in such a state of self-absorption. Within the sphere of everyday life, we adopt a modified self-certificationalism: A cognition is to be accepted as true unless defeated by countervailing considerations. That is to say, innocence, or an assumed warrantedness, is the epistemic default. Now this holds concerning the scripturally conveyed monistic cognition 'Brahman' (Brahman is everything). But also, Advaitins argue, Brahman cognition is in principle indefeasible, for two reasons. First, it is the proper province of scripture, and of scripture only, to tell us things of this order, as the sun (says Śaōkara, who is echoed in dozens of texts) is the proper illuminer of colour. Second, a proper challenger to Brahman cognition would similarly have to be about everything. But if a cognition were truly about everything (including itself) it would be identical with Brahman cognition. Thus there can be no challenger of Brahman cognition other than Brahman cognition itself, which is no challenger. Brahman cognition is both *prima facie* warranted (innocence is the justificational default) and *ultima facie* warranted, in that it cannot be challenged.

The monism of an all-inclusive Brahman as declared in the Upaniṣads is not the heart of the Advaita position, which is instead the psychological monism of self-awareness. But the two are related, as we can see by looking at another argument, namely that the *summum bonum*, popularly termed 'liberation' and by philosophers 'knowledge (or mystical experience) of Brahman' (*brahma-vidyā*), does in fact, when it occurs, reveal self-awareness to be the sole reality. The fundamental reason why scripture teaches that Brahman is everything is to provide a meditational support helpful in achieving the supreme good. There may seem to be some truth in the idealist view that Brahman is the ground and support of everything - indeed its material reality, as the material reality of a gold bracelet is just the gold - in that every appearance appears just to the self. However, there is no more truth in this view than in the theistic position that God is the creator and sustainer of things, a teaching also helpful for some. Scripture's purport is thoroughly soteriological; that is to say, it aims at bringing us to the realization of self-illumining self-awareness. Scripturally conveyed cognitions are sublated, like every cognition other than self-awareness itself, in the supreme experience. But the monism of an all-inclusive Brahman declared

by scripture is, within the sphere of spiritual ignorance (*avidyā*), a most helpful teaching for transcending spiritual ignorance - as well as one that is indefeasible by everyday experience and knowledge. (Advaita's exegetical strategy is similar, as suggested, with regard to Upaniṣadic teachings about God.)

There are more or less obvious problems with these arguments, problems that classical and modern opponents of Advaita have identified. We shall mention just a few. First, it is not clear that self-illumining self-awareness is nonsublatable experientially, particularly as Advaitins understand (experiential) sublation - that is, on analogy with an experiential correction of a perceptual illusion. A nonveridical perception of a snake is sublated and corrected by a veridical perception of a rope. For Advaitins, it seems to be the posteriority of the correcting perception that is key. Why then could not a fuller experience of self as embodied, or being in the world, follow a meditational experience of self-absorption? Second, Brahman is declared in the Upaniṣads to be bliss, among other attributions, not only self-awareness. Could there not be, then, a distinct challenger to the scriptural teaching about Brahman which was similarly about everything: for example, 'All-inclusive Brahman is not bliss?' And finally, there are Buddhists and others who say that the supreme mystical experience does not reveal a self, but, for example, a no-self. Whom should we believe?

3 Dialectical Advaita

Although Śaōkara and other early Advaitin philosophers concern themselves principally with the logic of illusion along with exegetical questions, they also launch dialectical attacks against rival schools, and specifically against the category of external relationality crucial to all realist and pluralist ontology. In the twelfth century, an Advaitin named Śrīharṣa ingeniously expands the earlier polemics, aiming in particular at the realist system known as Nyāya-Vaiśeṣika and purporting to dismantle it plank by plank. Śrīharṣa takes more seriously the all-inclusiveness and simplicity of Brahman presumed to be taught by scripture, and believes that the reality of Brahman means that it is impossible to define and explain coherently apparent diversities. He cashes out this commitment with an onslaught upon Nyāya's pluralist ontology, an onslaught in which attacks on relations figure prominently (see Nyāya-Vaiśeṣika §§4-5). Later Advaitins (including modern philosophers) rework some of his arguments to explode other views.

If there are two things *a* and *b* related by the relation *R* - thus *aRb* - in virtue of what is *R* related to *a*, and likewise to *b*? A second relation and a third, *ad infinitum*, would seem to be required. Śrīharṣa employs this logic (in the West sometimes called the Bradley problem (see Bradley, F.H. §5)) in a variety of contexts, for example, regarding the relation between a property-bearer and a property:

> If the property is unrelated to the property-bearer, there is an obvious problem; [if, on the other hand, it is related] there will be an endless number of relations and thus infinite regress. Or if at the beginning or the end the relation is admitted to be of the very nature of one of the terms [property or property-bearer], then since even the other term of the relation would enter into the very nature of that [the combined relatee-relator], nothing but nondistinctness would result.
>
> (*Khaṇḍanakhaṇḍakhādya*, 107)

Three options are sketched: (1) a property, such as blue, is unrelated to its bearer, such as a pot; (2) if there is a relation that relates them, such as inherence, then there have to be further relations to relate the inherence to each of the terms, the blue and the pot, *ad infinitum* (*aRb, aR′R, aR″R′R, ad infinitum*, likewise with the second term); unless (3) it is the very nature of one of the terms to link with the other: such linkage would amount to nondistinctness. The third seems the only viable option. Nondistinctness, however, is at odds with Nyāya pluralism, and thus the argument (along with others), Śrīharṣa concludes, shows that there is no coherent Nyāya challenger to the monism of Brahman taught by the Upaniṣads.

In sum, distinct things have to be in relation, but relations are impossible. Thus by presupposing fundamentally distinct things, pluralists run into a host of difficulties, as indicated by this demonstration of incoherence (and others). Gaōgeśa (*fl. c.*1325), a later logician of the Nyāya school, responds that it is an error to treat a relator as the same type of thing as its relatees, and it is this mistake that engenders the appearance of vicious regress. Of course, Advaitin followers of Śrīharṣa find further problems with the response, and the controversy, one of the finest preserved in Sanskrit, continues for several more centuries.

4 Theological monism

The cornerstone of the monism of Indian theism is found in an Upaniṣadic story of a father teaching his son about Brahman:

> Just being, my son, was this [universe] in the beginning, one alone, without a second. There are, to be sure, some that say, "Just non-being was this [universe] in the beginning, one alone, without a second. From that non-being, being arose." But how, my son, could it be so?… How from non-being could being arise? On the contrary, just being, my son, was this [universe] in the beginning, one alone, without a second.
>
> (Chāndogya Upaniṣad 6.2.1-2)

Here we find an early expression (700 BC?) of the metaphysical law *ex nihilo nihil fit*, 'nothing from nothing'. The Upaniṣads weave several fanciful stories about how the One becomes many, stories that are interpreted by later theologians as underscoring emanationism. God looses forth (*sṛjate*) gods, Vedas and Upaniṣads, humans, animals, plants, rocks and dust out of God's own substance. The universe is God's body.

Indian theists commit themselves to a thoroughgoing reality of a plurality of things; spiritual monism none the less provides an absolute boundary, or a resource, for their theorizing (except with the Dvaita, 'Dualist', Vedānta school). For example, evil, a challenge to any view that would uphold the goodness of a Creator (see Evil, problem of), has a different look within a theological monism as opposed to a theism that has God separate from the world, creating *ex nihilo*. God, being everything, shares in everyone's suffering; evil looks more like masochism than a matter of God's harming others. Moreover, God's being everything is thought to guarantee a universal harmony. It is impossible for society, for example, to disintegrate into chaos. If there were such a threat, God would appear (would be forced to appear) in a special manifestation, *avatāra*, to assure a return to harmony. This is a principal message of the *Bhagavad Gītā (Song of God)* and other theistic texts.

Finally, the monistic dimension of Indian theism spawns, in contrast with the illusionism of Advaita Vedānta and much Buddhism as well, a distinct attitude towards the body and physical things. Nature is enchanted, the body a mystic instrument. To be sure, asceticism, much admired in classical Indian society in accord with Advaita and Buddhist teachings, colours the religious practices of Indian theism. But worship and other practices reflecting belief in a divine immanence tend to prevail.

Monotheism

Judaism, Christianity and Islam are usually cited as the major monotheistic religions. These are religions which acknowledge only a single god, and which construe that god as transcendent - that is, as a being who is distinct from the ordinary world and superior to it. They also construe this god as a person or as very much like a person. The polytheistic religions agree with monotheism, for the most part, in construing the gods in personalistic terms, but they acknowledge a plurality of gods. Pantheists, on the other hand, usually accept the singularity of the deity, but reject the transcendence, identifying the deity more closely with the ordinary universe, perhaps as a certain aspect of the universe or as the totality of the universe considered in a certain way. They also are likely to reject the personalistic idea of the deity.

This entry will discuss some philosophical aspects of the contrast between monotheism and polytheism. There are different ways of understanding 'acknowledge' in the characterization of monotheism given above. One may believe that there exists only one god. Or one may believe that more than one god exists, but worship only one, or hold that it is wrong to worship more than one. A closely related issue concerns the concept of deity that is employed in such beliefs and claims. The 'high' Anselmian conception of Christianity's god - a being than whom no greater can be conceived - is only one account. Perhaps of most philosophical interest is the problem as to whether logical argument can demonstrate polytheism to be false and establish the truth of the Anselmian account.

1 Types of monotheism

Monotheism contrasts on one side with atheism and on the other with polytheism. Philosophers, initially at least, may take monotheism to be a doctrine to the effect that there exists exactly one god, no more and no less. Atheism, then, would be the doctrine that there exist no gods at all, and polytheism would be the claim that there are several gods (see Atheism §1). A monotheist would be a person who accepts the monotheistic doctrine, and similarly for atheists and polytheists.

All three of these 'isms', however, are ambiguous in an important way. Consider another contrasting pair of notions, which mark an important distinction among various social systems - monogamy and polygamy. Hardly anyone would take seriously the suggestion that we should construe a monogamist as a man who believes that there is only one wife, or that we should take monogamy to be the doctrine that one and only one wife exists. It would be much more plausible to construe monogamy simply as a practice - that of having only one wife - and a monogamist would then be a man who had only one wife. Polygamy, of course, would then be the contrasting practice of having more than one wife. And some people might want to add a somewhat more theoretical and doctrinal element to these conceptions, perhaps saying that monogamy includes a normative claim, the claim that it is not proper for a man to have more than one wife; polygamy would then involve the contrasting normative claim.

In an analogous way, there is a religiously important sense of monotheism in which it consists simply in having only one god - that is, in committing oneself to, worshipping, obeying, and so on, only one god. There is a second sense in which monotheism is the doctrine that there is something improper and illegitimate in worshipping more than one god (and perhaps also that there is something improper about not worshipping any god). And then there is a third sense, that in which monotheism is the doctrine that there exists one and only one god. These will be referred to in this entry as, respectively, *cultic monotheism*, *normative monotheism* and *descriptive monotheism*.

It is useful to keep these distinctions in mind when considering classical texts dealing with this general idea. Pre-Christian Judaism, for example, is often cited as an early example of monotheism, and indeed as the precursor of monotheistic Christianity. But consider a classic monotheistic Hebraic text, the first of the Ten Commandments: 'Then God spoke all these words: I am the LORD your God, who brought you out of the land of Egypt, out of the house of slavery; you shall have no other gods before me' (Exodus 20: 1-3). Pretty clearly, cultic monotheism is here being enjoined on Israel. They are to 'have' no other gods than the LORD (Yahweh). And perhaps the fact that this commandment is attributed to God himself may suggest that there is also a normative element in this monotheism. (Even so, this text would not support the view that it is improper for anyone to have more than one god, or one of those other gods. This command is explicitly addressed to Israel.) But the text seems to have no suggestion in it at all of descriptive monotheism. In fact, it may well be construed as positively envisaging the possibility of the existence of other gods.

Cultic and normative monotheism are logically compatible with descriptive polytheism, and apparently they are religiously compatible with it also. There have been, and probably still are, religions whose adherents clearly recognize the existence of gods to whom they themselves give no allegiance. An interesting and explicit biblical example comes from the monarchic period of Israel's history. In that story, some Aramean army officers undertake to explain to their king why they were defeated by the Israelites. 'Their gods are gods of the hills,' they say, 'and so they were stronger than we.' And they propose a different strategy for the next encounter: 'Let us fight against them in the plain, and surely we shall be stronger than they' (I Kings 20: 17-25). The Arameans of this story express no doubt about the existence of the Israelite gods - in fact, they attribute their own defeat to the power of those foreign gods in the hill country of northern Israel. But they themselves have no allegiance to those gods. They do not profess to worship them or to serve them. In fact, they are plotting to defeat them at the next opportunity, by fighting on the plains where their own gods are at home. These Arameans were descriptive polytheists with respect to the Israelite gods, and probably they were both cultic and descriptive polytheists with regard to another set of gods, their own.

2 Concepts of deity

If the story of the Arameans seems strange and awkward, this reflects the fact that the word 'god' (and 'God') involves an ambiguity similar to the one we have been considering. There is a sense of this word, fairly common now, in which it has a cultic element built into it. In this sense, to use the word 'god' to describe or identify some being is *ipso facto* to profess a certain attitude - worship, obedience, reverence, and the like - towards that being. Sometimes this cultic element is made explicit in something like a definition. Perhaps the best-known modern definition of this sort is that attributed to Paul Tillich (§3), that God is the object of ultimate concern. A person who accepted that account would speak paradoxically, to say the least, if they were to say 'Of course God exists, but he is of no concern to me.' Some students of early Buddhism, however, think that just this combination may well have been the view of Gautama the Buddha (see Buddha). They suspect that Gautama held that (perhaps only probably) there are gods, but that they have no concern with human life and so we need not concern ourselves with them. A similar view is sometimes attributed to Epicurus (see Epicureanism §9).

This raises a question about the concept of a god. Monotheism, polytheism and atheism differ with respect to the number of gods, but all are equally in need of some elucidation of the concept of a god. Anyone who professes one of these 'isms' seems to need some idea of the nature of a god. What sort of thing is it of which only one, or more than one, or none at all is supposed to be worshipped? What sort of thing is it of which there is just one, or more than one, or none at all? Throughout the Christian period, Western philosophical theology has gone very strongly to extremely 'high' conceptions of the deity. Perhaps the best-known formulation of a high conception is that of Anselm of Canterbury (§4), who understood God to be a being than whom no greater can be conceived (*Proslogion*, ch. 2). Whether this conception guarantees descriptive monotheism will be considered in §3 (see God, concepts of §§3-6).

For the moment, however, it is useful to recognize that there have surely been religions, and perhaps there still are some, that do not construe their gods in this high way. The Arameans referred to earlier certainly cannot have had anything remotely like Anselm's idea in mind when they spoke about gods, either their own or those of the Israelites. For they construed those gods as beings whose power would probably run out forty miles from home, in the transition from the hill country to the Syrian plains. The gods of pre-Christian Greek and Roman popular religion also do not seem to make a plausible fit with anything like the Anselmian notion. And so on. Is there any other notion of a god, something radically non-Anselmian, which would be applicable to a wide range of actual religions? Some philosophers think so. Richard Swinburne, for example, says 'I understand by a god a non-embodied rational agent of great power' (1970: 6). Probably the gods as the Arameans construed them, along with the gods of ancient Greece and Rome, and many others, would fit this definition fairly well. And so, for that matter, would God as he is construed in Christian theology. The Anselmian concept might be a more adequate account of the Christian deity, and perhaps a more interesting and provocative account. But God, as he is described by orthodox Christian theologians, would also satisfy Swinburne's definition. He too is a non-embodied rational agent of great power.

With reference to Swinburne's definition, then, the Arameans of the biblical story were probably doubly polytheistic in the descriptivist sense, believing in the existence of several gods to whom they owed allegiance and

also in the existence of several to whom they did not owe allegiance. The ancient Greeks and Romans were apparently also descriptive (and cultic) polytheists. Perhaps more interestingly, most Christians are descriptive polytheists in Swinburne's sense of 'god' because angels (and devils also) fit his definition perfectly well. But of course Christians are not, on that account at least, cultic polytheists. For though they often profess to believe in the existence of angels and devils, they do not characteristically profess to worship these beings.

Many Christians, of course, will feel uncomfortable with Swinburne's definition, and would not like to be identified as polytheists. This perhaps reflects the strongly cultic connotations which the word 'god' now has, especially when it is capitalized. These Christians, quite properly, do not want to be taken for worshippers of angels, or even for people who think that it might be appropriate to worship an angel. But they are, for the most part, content to be known as people who believe in the existence of angels. And being a descriptive polytheist, in Swinburne's sense of 'god', need not involve anything more than that.

3 Rationales for monotheism

The most common sort of rationale given for cultic monotheism is strongly religious in character. So in the Hebraic account, for example, God is said to have rescued the people of Israel from their bondage in Egypt, exercising his power on their behalf. He then makes a covenant with them, and one element of this covenant is that they will have no other god. The idea of this covenant is deeply embedded in the self-identification of this people. People who accept that self-identification as their own thereby accept a commitment to that deity. That god, and no other, will be their god.

Sometimes the commitment is made on a more personal level. The biblical story of Ruth, for example, is the story of a young widow who decides to leave her home in Moab and to move to Israel with her mother-in-law. Declaring her decision, Ruth says to Naomi, 'your people shall be my people, and your God my God' (Ruth 1: 16). She has made her decision to take up a new life in a new place and a new community, and part of that decision involves making a commitment to a new god and abandoning whatever commitment she may have had to the gods of Moab. She may have been a cultic polytheist in Moab, but now, she resolves, she will commit herself to the one god whom Naomi worships.

Rationales for descriptive monotheism often have a more philosophical flavour, appealing to more general principles, such as logic. They may thus be of more general philosophical interest. Especially for attempts to establish descriptive monotheism, it is crucial to fix somehow on the relevant concept of deity. And it is important also to remember that descriptive monotheism has a contrast on each side of it - atheism and polytheism. Establishing monotheism must involve ruling out both of these alternatives.

Perhaps it seems easiest to attack descriptive polytheism first. The most attractive strategy for this project is analytic or definitional. One looks for a concept of deity which is such that it would be logically impossible for more than one actual existent to satisfy it. Of course, Swinburne's concept will not be satisfactory for this purpose. There is nothing in it which rules out the possibility that several beings could satisfy it. But maybe there is some 'higher' concept which guarantees singularity.

Christian theologians have often included the attribute of omnipotence in their idea of God, and this may seem to provide a convenient connection with singularity (see Omnipotence §1). Initially at least, it is plausible to think that there could not possibly be two omnipotent beings. Which one would prevail, after all, if they came to blows? A little more formally, it might be thought that an omnipotent being ought to be able to overcome any external obstacle and also to thwart any external initiative. So, if there were two distinct omnipotent beings, *A* and *B*, then *A* should be able to overcome *B*, and *B* should also be able to resist *A* and thwart him. But that combination seems logically incoherent; if so, then it may constitute a *reductio ad absurdum* disproof of the suggestion that there could be two distinct omnipotent beings.

The concept of omnipotence, however, is itself surprisingly difficult to clarify, and that in turn generates a difficulty for this line of argument. At least since the time of Thomas Aquinas, most Christian theologians have construed omnipotence in such a way that it does not involve the power to do logically impossible tasks. Given this understanding of omnipotence, it is hard to see how to carry out the *reductio* successfully. Assume (for the *reductio*) that both *A* and *B* exist and are omnipotent. Perhaps it can then be assumed that the omnipotence of *A* should enable him to overcome any resistance offered by *B*. Well and good. But, on this understanding of

omnipotence, the failure of *B* to resist *A* successfully does not count against *B*'s omnipotence. For, on this reading, thwarting *A* is a logically impossible task. After all, *A* is omnipotent; he cannot be resisted. And the impossibility of the task removes it from the sphere of omnipotence. Therefore, the fact that *B* cannot succeed in the logically impossible project of resisting *A* does not represent a failure of omnipotence in *B*. There is no contradiction in the admission that *B*, though omnipotent, cannot thwart *A*. And so the *reductio* fails.

Suppose we reject the 'majority' view of omnipotence associated with Aquinas and opt instead for the minority view. On this view, omnipotence enables its possessor to do even those things which are logically impossible. Given this reading of omnipotence, *B* is not excused from the task of thwarting *A* merely because that task is impossible. But now the *reductio* runs into difficulty at a different point. For now we can say that *A*, being omnipotent, will certainly succeed in his project, and *B*, also omnipotent, will surely be able to thwart *A*. Of course, that seems thoroughly incoherent, the description of a logically impossible state of affairs. It entails that *A* both succeeds and fails to succeed, and also that *B* both succeeds and fails. But given the minority understanding of omnipotence, what would be the significance of discovering this logical incoherence or impossibility? After all, on the minority view, impossible things fall within the power of omnipotence. If *A* and *B* are omnipotent in the minority sense, then they may well be able to bring about this logically impossible state of affairs. Here too the attempt to construct the desired *reductio* seems to fail. As far as these arguments go, then, we are left with the possibility that there might indeed be two omnipotent beings.

On neither of these views of omnipotence, therefore, is it clear that we can rule out descriptive polytheism simply by including omnipotence in our concept of a god. We might, of course, try some other attribute which theologians generally include in a high conception of the deity. But in fact there would seem to be an easier way to succeed along these lines. We can simply attach an explicit singularity requirement, perhaps by adding the phrase 'the one and only', to some already formulated specification of a concept of deity. We can, for example, start with Anselm's account, and generate from it the revised formula 'the one and only being than whom no greater can be conceived'. Let us call this the 'singularity' concept of deity. If we adopt the singularity concept, then at least one half of the descriptive monotheist position is guaranteed. There is not, and there cannot be, more than one actually existent being who satisfies this description. Furthermore, we can say that if there is exactly one existing being who satisfies Anselm's original concept, then that same being also satisfies the singularity version. And if nothing satisfies Anselm's concept, then nothing satisfies the singularity version either.

This strategy, however, also costs something. It provides a comparatively easy way to rule out descriptive polytheism (for the chosen concept of deity, of course), but it makes it harder to rule out atheism. In the example just given, for example, we can notice that if two (or more) existent beings satisfy Anselm's concept, then nothing at all satisfies the singularity concept. For in that case there would be no being who was the one and only being than whom no greater can be conceived. There would instead be several beings who were tied for the position of maximal conceivable greatness. But, of course, none of these beings would satisfy the singularity requirement.

Anselm, of course, argued that there is an existent being who satisfies his concept - that is, that there actually is a being than whom no greater can be conceived. And there have been some impressive and provocative recent reformulations of the Anselmian line of argument (for example, Plantinga 1974). But neither Anselm nor his recent followers clearly address the question of whether there may be more than one being than whom no greater can be conceived. We might say, therefore, that if their arguments are successful they may refute 'Anselmian atheism' and establish Anselmian theism, where Anselmian atheism and theism are defined by reference to Anselm's concept of God. But there is also 'singularity atheism', which consists of the claim that nothing satisfies the singularity concept. The arguments of Anselm and his followers do not seem to refute singularity atheism. Consequently, they do not establish descriptive monotheism according to either the Anselmian or the singularity concept of deity.

There are, of course, other lines of argument that might be explored. We might specify, for example, that we think of God as the creator of the world, and then go on to argue that the universe exhibits so much unity that it is plausible to attribute it to a single creator. That strikes some philosophers as rather attractive. But David Hume (§6) suggested that it is just as plausible to think that the universe was created by a committee (1779: part V). So this line of argument is not convincing to everyone. In fact, it is likely that no sort of philosophical argument for descriptive monotheism will be universally attractive. If we are concerned about descriptive monotheism at all, it

might be just as well to rely here too on distinctively religious considerations, perhaps indeed on some appeal to divine revelation (see Revelation §§1-2).

Aquinas, T. (1266-73) *Summa theologiae*, trans. Fathers of the English Dominican Province (1911), Westminster, MD: Christian Classics, 1981, 5 vols.(A concise discussion and defence of descriptive monotheism by one of the greatest philosopher-theologians of the medieval period; see particularly Ia, q.11, a.3.)

Hume, D. (1779) *Dialogues Concerning Natural Religion*, ed. N.K. Smith, Indianapolis, IN: Bobbs-Merrill, 1947.(This is an extensive discussion and critique of arguments which purport to prove the existence of God on the basis of the order and design in the world.)

Plantinga, A. (1974) *The Nature of Necessity*, Oxford: Clarendon Press.(Much of this book consists of rather technical discussions of modal logic, but the chapter on the ontological argument (196-221) contains one of the most influential modern versions of that argument. It requires careful reading, but it is understandable without much background in modal logic.)

Swinburne, R. (1970) *The Concept of Miracle*, London: Macmillan.(This is mainly a discussion of the possibility of miracles, but it includes an interesting and provocative specification of the concept of a god.)

Montague, Richard Merett (1930-71)

Richard Montague was a logician, philosopher and mathematician. His mathematical contributions include work in Boolean algebra, model theory, proof theory, recursion theory, axiomatic set theory and higher-order logic. He developed a modal logic in which necessity appears as a predicate of sentences, showing how analogues of the semantic paradoxes relate to this notion. Analogously, he (with David Kaplan) argued that a special case of the surprise examination paradox can also be seen as an epistemic version of semantic paradox. He made important contributions to the problem of formulating the notion of a 'deterministic' theory in science.

Much of Montague's work in philosophical logic consisted in bringing the resources of possible worlds semantics to bear on metaphysical and logical problems. He pioneered the idea of generalizing possible worlds semantics to include tense logic and the logic of demonstratives, in which an expression is evaluated for truth not just at a possible world, but at an index consisting of a world, a time, a location, an addressee, and so on. He called this general framework 'pragmatics'. Constraining the indices in various ways yields traditional logics: limiting them to times alone yields traditional tense logic, limiting them to possible worlds alone yields traditional modal logic, and taking them without limitation yields a general kind of logic in which one may capture the interrelations, for example, of tense, modality and demonstratives. As part of this enterprise he studied different ways of formulating nonextensional notions, examining the connections between languages in which modal notions are captured by modal operators and languages in which these same notions are captured by explicit characterization of propositions. In the former, the sentence 'Necessarily, snow is white' has the form ' $\Box(\text{Snow is white})$'; in the latter it has the form ' $\exists p(p \ = \ \text{that} - \text{snow} - \text{is} - \text{white} \ \& \ p \ \text{isnecessary})$'.

Montague espoused the metaphysical reduction of problematic philosophical entities to constructions out of the metaphysical ingredients needed for possible worlds semantics. He assumes that properties are functions that map worlds to sets of entities, mapping each world to the set of entities that have the property in that world. He suggests that pains may be reduced to relations between persons and moments of time, that events may be reduced to properties of moments (or intervals) of time, and so forth. These reductions are to be justified by their logical fruit; for example, we can analyse 'an event of Caesar's running happened at *t*' as 'the property of being a time at which Caesar runs is possessed by *t*'. He extends this idea to mass terms - holding, for example, that 'water' denotes the property of being a body of water.

Montague's most influential work lies in the semantics of natural language. In 'Universal Grammar' (1970), he formulated a quite abstract, general framework for semantics, and in 'English as a Formal Language' (1970) and 'The Proper Treatment of Quantification in Ordinary English' (1973), he gave particular semantical systems that represent fragments of English.

'Proper Treatment of Quantification' contains the suggestion, contra Russell, that denoting phrases do have meanings of their own, but that they stand not for individuals but for intensions of sets of properties of individuals. An intension of this sort is a function that picks out from each possible world a set of properties, not necessarily the same set in every world. For example, 'no giraffe' stands for the function that maps each world to the set that contains each property of individuals that is not possessed by any giraffe in that world; then, 'No giraffe runs' is true in a world *w* just if the property of running is in the set to which that function maps *w*.

He used this idea to address the 'opaque' readings of transitive verbs, such as 'seek', which may take as objects terms which do not have an actual referent. Simplifying somewhat, the denotation of 'seek' (on this reading) is a relation between individuals (the seekers) and intensions of sets of properties, the sorts of intensions that will be denoted by a direct object of the verb 'seek'. With no additional constraints, this permits 'seek a unicorn' to be true of individuals who 'seek unicorns' without there actually being any unicorns; the seekers of unicorns in a world *w* are those individuals who are appropriately related (in *w*) to the intension that in every possible world picks out the set of properties possessed by some unicorn in that world. (The appropriate relation is not further defined; it is to be given by our understanding of the meaning of 'seek'.) An ordinary nonopaque verb has the same kind of logical form, but special principles (called 'meaning postulates') reinstate traditional inferences for them. For example, let *find** be the denotation of 'find', so that *find** is a relation between individuals (the finders) and intensions of sets of properties. Then a meaning postulate for the verb 'find' would be:

There is an ordinary relation, *find*, between individuals such that necessarily *find** relates (in world *w*) an individual *i* to an intension *P* of a set of properties just if the property of being a thing such that *i finds* it is a member of the set that *P* picks out in world *w*.

It is a consequence of this postulate that if you find a unicorn, then there is a unicorn that you find, but this consequence will not follow without the meaning postulate. Since there is no similar meaning postulate for 'seek', you may seek a unicorn without there being a unicorn that you seek.

These essays, particularly 'Proper Treatment of Quantification', led to a tradition dubbed 'Montague Grammar', in which one studies natural language by giving a rigorous semantics for a formal system that resembles a fragment of a natural language; much fruitful work has been pursued within this tradition, often based on some version of the 'pragmatic' model theory discussed above. This has been an influential element in the development of semantical work by theoretical linguists, as well as the popularity among philosophers and linguists of appealing to possible worlds in informal semantical accounts.

Montaigne, Michel Eyquem de (1533-92)

Montaigne was a sixteenth-century French philosopher and essayist, who became known as the French Socrates. During the religious wars between the Catholics and the Protestants in France, he was a friend and adviser to leaders of both sides, including the Protestant leader Henri de Navarre, who converted to Catholicism and became King Henri IV. Montaigne counselled general toleration for all believers, a view promulgated by the new king in the Edict of Nantes (1598). His main literary work was in the form of essais *(a word originally meaning 'attempts'), or discussions of various subjects. In these he developed various themes from the sceptical and Stoic literature of antiquity, and in his unique digressive way presented the first full statement in modern times of Pyrrhonian scepticism and cultural relativism. In particular, he presented and modernized the ancient sceptical arguments about the unreliability of information gained by the senses or by reason, about the inability of human beings to find a satisfactory criterion of knowledge, and about the relativity of moral opinions. His advocacy of complete scepticism and relativism was coupled with an appeal to accept religion on the basis of faith alone. His writings became extremely popular, and the English translation by John Florio, first published in 1603, was probably known to Shakespeare and Francis Bacon. Montaigne, whose essays provided the basic vocabulary for modern philosophy written in vernacular languages, was one of the most influential thinkers of the Renaissance, and his works are regarded as classics of literature and philosophy.*

1 Life

Michel Eyquem de Montaigne was born into a very well-to-do family. His father, Pierre Eyquem, was a Catholic merchant and his mother, Antoinette de Louppes, came from an important Jewish family which had fled to southern France from Spain towards the end of the fifteenth century. Montaigne studied at the Collège de Guyenne in Bordeaux, an elite institution that had been recently set up by Portuguese New Christian refugees (that is, Jewish converts to Christianity) to educate the new middle-class students in the city. (Montaigne's distant cousin, Francisco Sanches, the physician and sceptical philosopher, attended the same school, but not at the same time.) The teaching staff included the Scottish poet and theological leader, George Buchanan, and some of the leading Portuguese humanistic scholars of the period who had studied at the University of Paris. After being educated at the Collège, Montaigne may also have studied briefly at the University of Toulouse (where Sanches became a famous professor). Montaigne studied law, and became a magistrate and a counsellor to the *parlement* of Bordeaux. After a lengthy retreat from public life, followed by a period of travel to Switzerland, Germany and Italy, described in his *Journal de Voyage*, he was Mayor of Bordeaux from 1581-5. During the religious wars which divided France for a good part of the sixteenth century, Montaigne was a friend of many of the leading personalities of the Reformation and the Counter-Reformation in France, including Henri de Navarre, the Protestant leader who became the Catholic King Henri IV.

Montaigne's first work was a letter portraying the death in 1563 of his very close friend, Etienne la Boétie, who had written against slavery and for toleration, views Montaigne continued advocating after his friend's death. In 1569 he published a translation of the *Theologia Naturalis sive Liber Creaturarum (Natural Theology or Book of Creatures)*, a treatise by the Spanish theologian Raymond Sebond (Ramon Sibiuda, d. 1436), who had taught at the University of Toulouse, and who claimed that almost all of the Christian dogmas could be proved by rational means. Montaigne's father, who thought highly of the work, had requested that his son undertake this task. It was during his period of retreat from public life (1571-80) that Montaigne began writing on a variety of subjects. He presented his ideas in the form of *Essais*, and he was one of the first persons to introduce this literary style of expression. He was also one of the very first thinkers to write on philosophical subjects in French rather than in Latin, the standard language for philosophy and theology for centuries. In so doing, Montaigne had to create a philosophical vocabulary in French. His essays are usually very digressive, starting with a quotation, or a thought, and rambling on in different directions to related subjects. The first version of his *Essais* was published in 1580, and he added to and revised them in later editions. The final and most complete edition appeared posthumously in 1595.

2 Scepticism and fideism

Montaigne's philosophy has to be gleaned from various of the essays, for he was not a systematic thinker who

presented his views in didactic form. His longest essay by far, the 'Apology for Raymond Sebond' of which large parts were written 1575-6, is the most extended treatment of his philosophy. It was composed shortly after Montaigne had read the works of the ancient Greek sceptic, Sextus Empiricus, whose writings had been published in Latin in 1562 and 1569. At the same time he was undergoing a personal sceptical crisis, in which he found that everything he had previously believed was in doubt. Montaigne carved mottoes from Sextus' text in the rafter beams of his study, so that if he was attacked by any dogmatic thoughts, he could lean back and regain his sceptical outlook by looking at the ceiling.

The 'Apology' begins by saying that many readers, especially women, had asked Montaigne to explain and defend Sebond's views in the face of criticisms levelled against them. Montaigne then offered as the defence of Sebond that one cannot expect his reasons to be convincing when nobody else's reasons are defensible, and when nobody is able to achieve certainty through reasoning. In order to show this, Montaigne then proceeded to develop in a gradual manner the many kinds of problem that make people doubt the reliability of human reason. He pointed out that human beings believe that they are able to understand the cosmos without the aid of Divine Light, and that they alone of the creatures on the planet can comprehend the world which they think was made for their own benefit. But if human beings are compared with the animals, it is obvious that they have no special faculties that are lacking among the animals. The vaunted rationality of the human being is just a form of animal behaviour. To show this, Montaigne cited materials from Sextus Empiricus, including the story (attributed to Chrysippus) of the dog who is supposed to have worked out a disjunctive syllogism. Montaigne further contended that even religion appears in animals as well as people, citing evidence that elephants seem to pray.

The comparison of animal abilities to those of humans presumably creates doubt about human intellectual pretensions. Montaigne contrasted the glories of the animal kingdom with the vain, stupid, immoral activities of human beings. Our so-called knowledge has not helped us to create a better world or to solve our problems. In spite of all our learning we are ruled by bodily demands and passions. What we consider our wisdom is just presumption which achieves nothing for us. 'The plague of man is the opinion of knowledge. That is why ignorance is so recommended by our religion as a quality suitable to belief and obedience' ([1563-92] 1957: 360). Wisdom has never actually helped anyone. On the other hand, the recently discovered natives of Brazil, the noble savages, manage to live in admirable simplicity, uneducated, with neither laws nor kings nor religion. Each society's laws are just the product of customs, with no genuine basis in reason. People are Christians in France and Muslims in Turkey by the accident of where they were born. So, according to Montaigne, one should take seriously the Christian message that we should cultivate complete ignorance and believe by faith alone. 'The participation that we have in the knowledge of truth, whatever it may be, has not been acquired by our own powers. God has taught us… his admirable secrets. Our faith is not of our acquiring, it is a pure present of another's liberality' ([1563-92] 1957: 369). Montaigne then quoted St Paul (I Corinthians 1) to the effect that God 'will destroy the wisdom of the wise, and bring to nothing the understanding of the prudent', and will save those who believe 'by the foolishness of preaching'.

After this introduction to scepticism and advocacy of complete fideism, Montaigne turned to the arguments from Sextus Empiricus about Pyrrhonian scepticism, and explained their value for religion. The Pyrrhonists, he insisted, are not negative dogmatists like the Academic sceptics. The Pyrrhonists suspend judgment about all propositions or assertions, even the one that says all is subject to doubt. They oppose all knowledge claims, and if their opposition has merit, it shows the ignorance of the opponent. Alternatively, if it has no merit, then it shows the ignorance of the Pyrrhonists. In either case, human ignorance must be acknowledged. Once the state of complete doubt is reached, these sceptics then live according to nature and custom. This state is the finest human achievement, and is the one that is most compatible with religion, for the human being becomes 'a blank tablet prepared to take from the finger of God such forms as he shall be pleased to engrave on it' ([1563-92] 1957: 375) (see Pyrrhonism).

These ancient sceptics had not only reached the summit of human wisdom, they also unknowingly provided a defence for Catholicism against the Reformation. If a person has no positive views, they cannot have wrong views. The sceptics, accepting the laws and customs of their society, would naturally accept Catholicism (as the customary religion of sixteenth-century France), and would have no reason for changing their faith. Moreover, the complete sceptic is in the perfect state to receive whatever revelation God cares to give.

3 Philosophical scepticism

Montaigne contrasted his monumental picture of Pyrrhonism with the deplorable history of dogmatic philosophers whose endless disputes and heterodox views exhibit nothing but human stupidity and credulity. In the best tradition of Renaissance humanists, Montaigne cited the vast range of opinions of ancient thinkers from Greece and Rome that had recently been discovered (see Humanism, Renaissance §1). In view of the enormous diversity of points of view, can one really determine what to believe or to accept as true? In all fields of inquiry the dogmatists have finally had to confess their ignorance, and their inability to come to definitive and unquestionable conclusions. Indeed, even the Pyrrhonists have fallen into the trap of asserting that they doubt, when what they need is a negative non-assertive language. It is better to question, and ask 'What do I know?' ('Que sçay-je?'), a phrase that Montaigne adopted as his motto (see Scepticism, Renaissance §5).

After surveying all kinds of philosophy, from ancient times to the present, Montaigne concluded that 'philosophy is but sophisticated poetry' ([1563-92] 1957: 401). He also used the information presented by explorers ancient and modern concerning the great variety of customs and behaviour in different parts of the planet in order to raise the question of whether there was any way of determining right or true standards, or whether one had to recognize that customs and behaviour just are relative to the cultures in which they occur.

Science fared no better than philosophy and morality. What thinkers have been offering through their theories are just human inventions, and philosophers never find out what actually happens in nature. What occurs is that some traditional opinions have been taken as authoritative, indubitable principles. Questioners are told that one cannot dispute with people who deny first principles, but, Montaigne observed, 'there cannot be first principles for men, unless the Divinity has revealed them; all the rest - beginning, middle, and end - is nothing but dreams and smoke' ([1563-92] 1957: 404). Even the new scientists of the Renaissance such as Copernicus or Paracelsus are just offering personal opinions that will probably be replaced by other people's opinions at some future time.

Having built up a general sense of why one should be a sceptic, Montaigne finally turned to the fundamental philosophical reasons for accepting the Pyrrhonian view that all is in doubt. These concern the unreliability of information gained by the senses or by reason, and the inability of human beings to find a satisfactory criterion of knowledge. Montaigne argued that if the dogmatists claim that human reason can know and understand things, they should show how in fact this occurs. If the claim is that sense experience provides this knowledge and understanding, the dogmatists should make clear what it is that we actually experience and whether we do in fact experience the very things that we think we experience. In fact, the senses are clearly subject to illusion, and we ourselves are constantly changing as our physical and emotional conditions alter. Once it becomes clear that the senses are full of uncertainty, the dogmatists will appeal to reason, but 'no reason can be established without another reason'. The dogmatists will have to provide a criterion of right reasoning, and a criterion of the criterion, and so on *ad infinitum*.

Montaigne suggested that people should suspend judgment on all matters, and then wait until God reveals principles to them. Until then, he said, one should just follow customs, traditions and social rules undogmatically, and one should be tolerant of other people's views. Religious beliefs should be based solely on faith rather than on dubious evidence (see Faith §§4-5).

4 Influence

Montaigne's rambling presentation of Pyrrhonian scepticism quickly became the best known and most influential statement of this view. Francis Bacon, Descartes, and Pascal, among other readers, were greatly influenced by him. His pleasant literary presentation of the sceptical attitude as well as the arguments behind it effectively provided many with a basis for rejecting the entire intellectual world of the time. He also provided reasons for accepting the status quo: his advocacy of accepting customary views because there was no adequate reason to change them became a defence of Catholicism against the Reformation during the seventeenth century in France. Leading churchmen, such as Bishop Jean-Pierre Camus, the secretary of St François de Sales, and Father François Veron, the official defender of the faith under Louis XIV, employed sceptical arguments as 'a machine of war' to defeat the intellectual claims of the Calvinists. On the other hand, Montaigne's leading disciples, Pierre Charron, Marie de Gournay, and François de La Mothe Le Vayer, are usually treated as being *libertins érudits*, possible secret non-believers in any form of Christianity, whose scepticism prefigured that of the Enlightenment, and who were

really trying to undermine religion.

The question of what Montaigne himself actually believed has been debated for the last four centuries with some interpreters insisting that he was trying to undermine all belief, including any religious belief, and other readers insisting that he was a genuine Christian believer who was offering a sceptical defence of Catholicism in the age of the Counter-Reformation.

It is extremely difficult to determine the actual views of someone centuries after he lived, and we have conflicting testimonies from his friends and from early readers. We know that Montaigne came from a family whose views encompassed the main religious beliefs of the time. His mother was half Jewish, and it has been suggested by Donald Frame that his tolerant, cosmopolitan, humanistic attitude may in part have been derived from his Jewish heritage (Frame 1965: 28). His father was a Catholic, and he had Protestant siblings. He was related to leading Calvinists in Belgium as well as to some important Catholics in France. He reported in his *Journal de Voyage* that when he visited Rome the Catholic censors seemed quite pleased when they read the manuscript of the first draft of the *Essais*. At the time they actually invited the author to stay in Rome and to 'assist the Church with [his] eloquence'. (The *Essais* were put on the Index late in the seventeenth century, principally because of Montaigne's suggestion that elephants engage in prayer.) Montaigne turned down the invitation, preferring retirement at his chateau near Bordeaux where he could gently muse about the human comedy, and discuss it in his many essays. He said at one point that in the essays 'I paint myself'.

What kind of a self was thereby indicated? Commentators have offered all sorts of readings. Without going into details about these many kinds of interpretations, it can be said that the sceptical fideism that is offered in the 'Apology for Raymond Sebond' is compatible with both a religious and an irreligious evaluation of the author's intentions, as either defending or undermining Christian belief. Essentially Montaigne's avowed fideism rests upon a *non sequitur*, namely that since all is in doubt, we should therefore accept Christianity on faith alone. This has been said by extremely religious persons like Pascal and Kierkegaard. And it has been said, presumably ironically, by agnostic or irreligious thinkers like Hume. In evaluating people who make this fideistic assertion we usually appeal to other information about their character and their activities in order to ascertain whether or not they are being sincere. Montaigne does not appear to have been particularly devout or fervent in his religious life, and his own acceptance of Catholicism seems tepid. He was generally interested in the variety of religious experience, ancient and modern, but he appears to have been indifferent to the major spiritual tendencies of his day, and was much more concerned with creating a peaceful social world in which all people could believe and practice what they wished. He was active in trying to bring about toleration of different religious practices and views, and he opposed and ridiculed different kinds of religious fanaticism and superstition. Pascal, who was very much influenced by reading Montaigne's *Essais*, considered him a sceptical non-believer who exhibited the misery of man without God. However, Montaigne himself said that to philosophize is to learn to die, and his sceptical outlook may have prepared him to live undogmatically in a troubled world, and to accept whatever might come afterwards.

Montesquieu, Charles Louis de Secondat (1689-1755)

Montesquieu, one of the greatest figures of the Enlightenment, was famous in his own century both in France and in foreign lands, from Russia to the American colonies. Later generations of French philosophes *took for granted his concern to reform the criminal laws, to replace the Inquisition with a reign of tolerance, and to repudiate the vicious conquests of the Spaniards in the Americas. They also accepted his finding that Protestant, commercial, and constitutionalist England and Holland represented all the best possibilities of Europe; whereas Catholic, economically backward, and politically absolutist Portugal and Spain represented the worst of the Western world and constituted a warning to the French.*

Although the findings and specific reforms proposed by Montesquieu were repeated by many another figure of the French Enlightenment, his work in certain respects remained unique in the circles of the most advanced thinkers. In his efforts to think systematically about politics and to do so by employing the comparative method, he stands virtually alone in his age. Other thinkers sharing his commitments resorted to the universalizing language of natural rights when they ventured into the realm of political philosophy. Or, like Voltaire, they tied their thoughts about politics to a succession of specific issues, each essay bearing so indelibly the imprint of specific time and place that there was no room for theory in their writings. Finally, as is true of Diderot or D'Alembert, many of the philosophes *were slow to recognize what Montesquieu knew from the outset, that if Enlightenment does not extend to politics it is futile.*

Steeped in Montaigne's scepticism, Montesquieu found that in the absence of absolutes there were good reasons to appreciate the 'more than/less than' and 'better than/worse than' judgments of comparative analysis. In his notebooks he commented that the flaw of most philosophers had been to ignore that the terms beautiful, good, noble, grand, and perfect are 'relative to the beings who use them'. Only one absolute existed for Montesquieu and that was the evil of despotism, which must be avoided at all costs.

Montesquieu wrote three great works, each teaching lessons about despotism and freedom,The Persian Letters (1721), the Considerations of the Grandeur of the Romans and the Cause of Their Decline (1734), and The Spirit of the Laws (1748).

1 *The Persian Letters*

A year before his death Montesquieu wrote a new preface to *The Persian Letters* (first published in 1721). Looking back, he recommended that the letters be read not individually but in their interconnections, since they are held together by a 'chain'. The letters form 'a kind of novel'; they tell a story and that story is the meaning of the book. Hence he repeatedly refused requests to add new letters, because more letters would signify less meaning.

As the story begins we learn that Usbek, a Persian, is travelling in the West with his countrymen Rica and Rhedi. The letters we read are exchanges among these tourists or between them and the persons they have left behind; many of the letters are the correspondence of Usbek with his wives or with the eunuchs who govern the household in his name during his absence. Between the first letter and the last, some nine years pass, during which the Persians learn much about Europe. The more they understand a foreign culture, the more they gain insight into their own as well. One cannot imagine a more entertaining or convincing argument for the comparative method than that which Montesquieu sets forth by example in *The Persian Letters*.

As Montesquieu indicated in 1754, his strategy was to portray the 'genesis and development' of the ideas of the Persians. Initially the Oriental visitors comprehend little of what they observe, so their earliest commentaries afford Montesquieu ample opportunity to satirize Western ways, as when Rica naïvely writes that the Pope is a magician who has the king believing that three are one and that bread is not bread, wine not wine. Eventually the Persians become so familiar with Western mores, customs, science and philosophy that the 'otherness' of Europe fades into their pasts. At the same time, however, their native Persia seems ever more foreign and even hideous from the standpoint of their transformed beliefs. When he first stepped foot on European soil in Italy Usbek sensed, 'even in the most insignificant of details, something that I feel and cannot express'. Later he and his comrades come to realize that it is freedom they have encountered in their new environment, and that for them to utter the word 'freedom' in reference to the West is inevitably to speak of 'despotism' when designating their own

country.

Virtually alone in his circle, Montesquieu recognized that to hold enlightened beliefs is not necessarily to be a tolerant person. Who could be more of a *philosophe* than Usbek, author of the most intellectually sophisticated of the Persian letters? And who could have better intentions than this same Usbek who dared to carry truth to the court of the Persian king, in consequence of which his days would have been numbered had he not found an excuse to visit foreign countries? Yet Usbek, after writing a series of letters diagnosing the malady of Oriental despotism, turns around and demands that his eunuchs initiate a reign of terror against his wives.

Jealousy is Usbek's undoing, a jealousy that must not be mistaken for the reverse side of love, because, as Usbek admits in an unguarded moment, he is incapable of loving his wives. In Persia women are the property of men; and although a man may fear losing his woman, exactly as he is disturbed by the loss of any of his prized possessions, it is impossible for him to love a creature who by the very nature of the mores and laws is not fully a human being. Near the end of the novel Usbek, provoked to hear of growing disorder in his seraglio, decides to return to Persia in order to reclaim his possessions, and in the meantime he deputizes the chief eunuch to rule his wives by fear and terror.

Far from an island of peace and contentment, the Persian family is a replication in miniature of the most insidious characteristics of the surrounding society and polity. Where Oriental despotism reigns, the family, too, is despotic. It is the curse of arbitrary power that it infects all human relationships, affairs of the heart no less than affairs of state.

Self-deception is a recurring theme in the novel. Usbek has come to know Oriental despotism for what it is, but he lacks the strength to apply the lessons he has learned to his personal relations. The wives are even more determined to avoid the truth. Slaves by the laws of their country, they prefer to regard themselves as enslaved by their love of Usbek. Only the eunuchs stand outside the web of self-deception; they, in order to feel less diminished by castration, dominate the women by self-consciously manipulating oppressive Persian notions of virtue.

The story ends with the suicide of Roxane, the one woman who mattered to Usbek. By holding herself aloof and refusing to be treated as property, she aroused Usbek's ardour. During his absence Roxane avenges herself by taking a lover and dies by her own hand rather than submit to Usbek's despotic rule. Her act proves a truth Usbek himself had enunciated, that under despotism everyone loses, the despot as well as his long-suffering subjects. It was Usbek who proclaimed that systematic injustice is self-destructive, little realizing that he would one day demonstrate his point at his own expense.

2 The *Romans*

Montesquieu's monograph on the Romans, *Considerations of the Grandeur of the Romans and the Cause of Their Decline* (1734), usually figures in modern scholarship as a warming up exercise for the causal reasoning found in his magnum opus, *The Spirit of the Laws* (1748). Such an interpretation is not incorrect but it is wanting in so far as it permits his third book to define the meaning of his second, as if his *Considerations on the Romans* had no significance in its own right. One might do better to see his second major publication as a variation on the theme of his first book. Previously he had argued that because of its internal injustice Oriental despotism is inherently self-destructive. Now he adds that the ancient Roman republic, though sometimes reasonably just internally, destroyed itself through the unrelenting external injustice of its foreign policy.

Montesquieu's Romans knew 'not even the justice of brigands'. After inflicting military defeat upon a prince, they exacted excessive war reparations that left him with no choice but to collect exorbitant taxes - 'a new kind of tyranny that forced the prince to oppress his subjects and lose their love'. Similarly, the Romans destroyed Carthage, 'saying they had promised to save the people but not the city itself'. Whenever possible the Romans fostered factional strife so as to weaken and eventually conquer foreign cities. 'If princes of the same blood were disputing the crown, the Romans sometimes declared them both kings. If one of them was under age, they decided in his favour'. A city that lost its battle with Rome inevitably found itself compelled to fight with Rome to subdue another people, after which the Romans stripped their erstwhile allies of their remaining freedoms. These practices of the Romans were 'in no way just particular actions occurring by chance; these were ever-constant principles'.

If nothing could sound more Machiavellian than Montesquieu's Romans, that is because his account of ancient history is taken directly from the great Florentine's *Discourses on Livy* (see Machiavelli, N.). Why not follow the lead of Machiavelli in turning the Roman senators into the most Machiavellian of ruling classes if to do so is the best way to discredit power-politics? Each Roman conquest, Montesquieu insisted, brought Rome that much closer to the day when the republic would perish, and Rome would begin to terrorize itself in much the same manner as it had long terrorized other city-states.

The more Rome expanded, the less it could sustain the integrity of its republican way of life. Civic mindedness yielded to civic neglect; private pursuits replaced public concerns. Frugality gave way to luxury and ostentation when returning soldiers carried plunder and foreign mores back to Rome. Removed from Rome for ever longer campaigns, soldiers no longer identified with their city but rather with their commander who offered them riches in return for their assistance in elevating him to political power.

Faced with evidence that the ruthlessness of the senators had added the name of Rome itself to the list of republics undone by Roman imperialism, Machiavelli hastened to place the blame on *fortuna*, which eventually undoes even the best laid plans. Montesquieu countered by denying that chance had anything to do with the demise of the republic. What was at work, he insisted, was nothing less than the operation of causal necessity. Any republic which grows beyond a certain point necessarily undermines its civic culture. Since the republic had to perish, it was only a question of how, and by whom, it was to be overthrown.

> It is not chance that rules the world…There are general causes, moral and physical, which act in every [regime], elevating it, maintaining it, or hurling it to the ground.
>
> (*Considerations on the Romans*, chaps 11, 18)

Montesquieu's objective in the *Considerations* was to set forth a causal argument that eliminated not just *fortuna* from historical explanation but Providence as well. Bishop Bossuet had preceded Montesquieu both in accepting Machiavelli's reading of Roman history and also in drawing the conclusion that the Roman republic destroyed itself by the systematic injustice of its foreign policy. Dedicated to vindicating the Christian view of history, Bossuet in the *Discourse on Universal History* (1681) deliberately set out to expunge pagan *fortuna* from the historical record. To that end he announced that 'the true science of history' was one in which the investigator identified the underlying causes which account for the revolutions of empires. Those causes turn out to be much the same as the ones cited later by Montesquieu, especially the decline of civic life and the demise of the large, frugal, agrarian middle class which, as Aristotle noted, was the backbone of a popular republic.

When Montesquieu approached Roman history he found that Bossuet had prepared the way for his *Considerations*. Specifically, the good bishop had driven *fortuna* off the historical stage and effectively pleaded the case for causal reasoning. All Montesquieu had to do to arrive at a historical science fit for the Enlightenment was to bracket off Providence as an unnecessary hypothesis, and with that act he had moved to a stage of thought which was both post-pagan and post-Christian.

3 The *Spirit of the Laws*

The centrepiece of Montesquieu's most comprehensive and systematic treatise is its typology of sociopolitical forms. Monarchy in politics is matched in society by an ethos revolving around the 'principle' of aristocratic honour; Oriental despotism is characterized by the principle of fear; and the ancient republic was enlivened by civic virtue.

By 'monarchy' Montesquieu understands feudal government in its final incarnation during the Old Regime. Absolute in theory, the power of the king is thwarted in fact by 'intermediary bodies' - the first and second estates (clerics and nobles) and the *parlements*, which were judicial institutions, not legislative bodies. Corporate and hierarchical, the social order is so thoroughly under the sway of the privileged estates that the members of the middle class, far from challenging the aristocrats, want nothing more than to amass enough wealth to buy a noble title and to pay someone - as did Molière's bourgeois gentleman - to teach them how to put on aristocratic airs.

Voltaire believed that *The Spirit of the Laws* was in reality nothing more than an apology for the privileged classes to which Montesquieu, a noble and former member of the Bordeaux *parlement*, belonged. The ancient republic was something lost and gone forever, and Oriental despotism was not only the worst of all possible worlds but a

constant reminder that to remove the intermediary bodies from a monarchy is to invite disaster. Hence, Voltaire concluded, Montesquieu was a formidable apologist for all the abuses of the Old Regime. If Montesquieu championed the English example, Voltaire assumed the hidden agenda was to suggest that power be taken away from the French monarch and turned over to nobles seated in a legislature.

Modern historians, Marxists and all those who wish for a ready-made link between social and intellectual history, have repeated Voltaire's charges. It is therefore crucial to note that other *philosophes* refused to follow Voltaire's lead, and to ask why. The best place to begin our reexamination of *The Spirit of the Laws* is with the recognition that, in its pages, England figures not only as the most free country in the world but also as the only monarchy that no longer possesses intermediary bodies, whereas Spain is portrayed both as the nation in which the intermediary bodies could not be more powerful and as a country plagued by a peculiarly Western variety of despotism.

'Abolish the privileges of the lords, the clergy, and cities in a monarchy', wrote Montesquieu, 'and you will soon have a popular state, or else a despotic government'. Although in despotism Montesquieu found nothing but evil, he did have considerable sympathy for the popular state that had emerged from the ashes of a feudal past. 'The English, to favour their liberty, have abolished all the intermediate powers of which their monarchy was composed.' During the upheavals of the seventeenth century, the remnants of feudalism perished in England, with the consequence that in Montesquieu's day the English had a monarch but no Old Regime. England was the first new nation.

Call England a monarchy and Montesquieu will not object, for such it once was and such it still is on the surface. But on a closer look England is much better described as a 'republic hiding under the form of a monarchy'. Unlike the republics of antiquity, but like Holland across the Channel, England is a commercial republic. Politically, however, there is a significant difference between Holland and England: the Dutch live in a confederate republic, the English in a centralized republic.

As a result of purging the feudal 'intermediary bodies' England is, at one and the same time, the most free country and the one in which freedom is in greatest danger of declining into its opposite. No sooner has Montesquieu applauded English liberty than he issues a stern warning: the English 'have a great deal of reason to be jealous of this liberty; were they ever to be so unhappy as to lose it, they would be one of the most servile nations upon earth'. Under the conditions of a post-feudal world, where power is centralized as never before, only a 'system' of liberty will suffice, a constitutional structure wherein there is a sharp separation of legislative, executive and judicial functions. In the famous Book XI, chapter 6, Montesquieu outlines his proposal for a system of freedom and deems it especially appropriate for the British; in Book XIX, chapter 27, he makes it clear that the spoils system (of Robert Walpole) is what actually exists in England.

Whatever his misgivings about England and Holland, Montesquieu was convinced that they were not only the most free but also the most powerful nations. Each age, he remarked in his notebooks, has its spirit, and the spirit of the modern age is that of commerce. Conquests weaken the conqueror, trade strengthens the most economically progressive nations. Both Holland and England are small; neither has much of a standing army; and yet these two commercial nations may well be the most formidable powers of Europe.

Altogether different is the situation of once proud Spain. Fields lie uncultivated, trade is nonexistent, and the Spaniards sit by idly while 'the rest of the European nations carry on in their very sight all the commerce of their monarchy'. It is the very power of the 'intermediary bodies', the nobility and the clergy, that accounts for the increasing powerlessness of the nation which in early modern history had been the leading country in Europe. The Church does nothing with its ever growing holdings of land, nor do the nobles produce anything since the aristocratic code of honour forbids titled persons to engage in commercial activity.

Enrichment through plunder, conquest, and murder is 'honourable'; indeed, it is holy as well when combined with forcible baptism. Thus the Church blessed the bloody conquests of greedy and cruel Spanish nobles in the Americas, as did the state which, following a mercantilist policy, was only too happy with the mounds of gold the conquistadores shipped back to the old world. Which is to say, the Spaniards mistook a symbol of wealth for wealth itself. As the quantity of gold in the king's coffers piled up, the value of gold declined: 'Spain behaved like the foolish king who desired that everything he touched might be converted into gold, and who was obliged to beg

of the gods to put an end to his misery' (*The Spirit of the Laws*, XXI, ch. 22). Well in advance of Adam Smith, Montesquieu declared that the wealth of nations depended on the production of goods and services.

A regressive economy was one consequence of the influence of Spain's powerful intermediary bodies; the Inquisition was another. That the French government might well follow Spain in permitting the Catholic Church to dictate oppressive public policies, even at the cost of undermining the power of the state, was indicated, Montesquieu believed, by the Revocation of the Edict of Nantes (1685). The Huguenots sent into exile by Louis XIV were the most able economic producers in France; in eliminating them Louis inflicted serious damage on the economic resources without which there can be little political power. Let the heirs of Cardinal Richelieu talk as much as they wish about reason of state; policy will never be reasonable when the king's confessor advocates the destructive measures dictated by the fanatical politics of divine right.

From his earliest writings to his last, Montesquieu was constantly attentive to Spain, the country which was a living example of what form despotism was likely to assume in the Western setting. In the Orient it is the absence of intermediary bodies that makes despotism so devastating. In the Western world it is the very triumph of those same bodies that fosters a less overt and less total despotism but a despotism nonetheless.

When Montesquieu looked to Spain and England he saw countries which, like France, had evolved from the embryo of a feudal past. Both those countries were further down the road of historical development than his native land. Would France duplicate the Spanish example, as Montesquieu feared? Or would it break with its feudal past, as had England? The best possibility, to Montesquieu's mind, was for France to chart its own course, one that would be constitutionalist, assuredly, but more politically decentralized than the British government. How to accomplish this task of reconstruction, he was the first to admit, was far from obvious. Surely the Catholic Church would not readily relinquish its stranglehold in France, nor would the nobility readily learn how to succeed economically or how to share political power. Historical and comparative analysis tell us what our problem is; they provide no easy solutions.

4 Legacy and reputation

The *philosophes* regarded Montesquieu, quite rightly, as an eloquent and penetrating spokesman for the outlook of the Enlightenment. For Diderot and D'Alembert, editors of the *Encyclopédie* (1751-72), it was a great victory for the party of humanity that the illustrious Montesquieu agreed to submit an article on taste to their undertaking in collective and committed publication. Yet most of the *philosophes*, despite their admiration of *The Spirit of the Laws*, denied that climate, a physical rather than a 'moral' cause, played the dominant role in the non-Western world that Montesquieu attributed to it. Frequently, too, the *philosophes* displayed some impatience that Montesquieu spent so much time discussing what is, when they were more interested in what ought to be.

In the nineteenth century Hegel, who acknowledged his intellectual debts, praised Montesquieu as superior to other writers of his age in taking an historical approach to his subject matter and in 'always treating the part in its relation to the whole'. Among noteworthy French authors Benjamin Constant's writings make incessant use of insights and formulations gleaned from Montesquieu; this includes Constant's frequently cited *Liberty of the Ancients Compared with that of the Moderns* (1819). Not only did Constant agree with Montesquieu in championing modern notions of freedom as privacy, but the two writers were alike again in their estimation that the freedom to pursue our individual desires will never be safe if we completely abandon the public and civic conceptions of liberty which prevailed in antiquity.

Finally, Tocqueville must be mentioned. His entire manner of conducting comparative analysis is reminiscent of *The Spirit of the Laws* (1835), and the specific objective of *Democracy in America* (1840), to fathom the political, economic, social, and cultural possibilities of a post-feudal republic, is already present a century earlier in Montesquieu's examination of England.

There are signs that the scholarship of our age is finally removing the onus with which Voltaire burdened Montesquieu's reputation. No longer is it common to see Montesquieu diminished to the lowly stature of an apologist for the privileged orders of his day. Unquestionably, he now figures as a far more profound thinker than Voltaire, and has begun to compete with Diderot and Rousseau for the title of the greatest French thinker of his time. Despite the historical specificity of his method, Montesquieu continues to speak to all persons who adhere to the ideals and aspirations of the Enlightenment.

Moore, George Edward (1873-1958)

G.E. Moore was one of the most influential British philosophers of the twentieth century. His early writings are renowned for his rejection of idealist metaphysics and his insistence upon the irreducibility of ethical values, and his later work is equally famous for his defence of common sense and his conception of philosophical analysis. He spent most of his career in Cambridge, where he was a friend and colleague of Russell, Ramsey and Wittgenstein.

The best-known thesis of Moore's early treatise on ethics, Principia Ethica (1903), is that there is a fallacy - the 'naturalistic fallacy' - in almost all previous ethical theories. The fallacy is supposed to arise from any attempt to provide a definition of ethical values. The validity of Moore's arguments is much disputed, but many philosophers still hold that Moore was right to reject the possibility of a reductive definition of ethical values. The book is also renowned for Moore's affirmation of the pre-eminence of the values of Art and Love.

Moore's later writings concern the nature of the external world and the extent of our knowledge of it. In opposition to idealist doubts about its reality and sceptical doubts concerning our knowledge of it, Moore defends 'common sense' by emphasizing the depth of our commitment to our familiar beliefs and criticizing the arguments of those who question them. But although he insists upon the truth of our familiar beliefs, he is remarkably open-minded concerning their 'analysis', which is intended to clarify the facts in which their truth consists.

1 Ethics

Moore studied philosophy at Cambridge University in the 1890s. At this time the idealist philosophy of F.H. Bradley was the dominant influence within British universities, and, under the influence of J.M.E. McTaggart, Moore became a disciple of Bradley. After graduating in 1896, however, Moore began to turn against the idealist tradition in philosophy. His first writings concern the foundations of ethics, and in the course of a critical study of Kant's ethical theory Moore argued that the idealist programme was deeply flawed: it was, he thought, a mistake to suppose that the fundamental principles of ethics require justification by reference to the will, reason or any similar criteria (see Kant, I. §9; Kantian ethics §1). For they concern a domain of values which is as objective as any physical fact, though Moore held that ethical values are not themselves physical or 'natural' facts; in his view the fundamental truths of ethics are abstract necessary truths concerning the intrinsic value of different types of state of affairs. He famously propounded this position in *Principia Ethica* (1903), where he argued that there is a fallacy, the 'naturalistic fallacy', in all theories which offer naturalistic accounts of ethical values and that much the same fallacy afflicts idealist theories of value. Moore assumed that such accounts always involve a definition, or analysis, of ethical value, so the thesis he sought to establish was that goodness, which he believed to be the fundamental ethical value, is indefinable. His main argument was that any supposed definition of goodness (for instance, as that which we desire to desire) can be seen to be incorrect when we recognize that it incorporates a substantial ethical thesis (for example, that whatever one desires to desire is *ipso facto* good). For, Moore maintained, if the original definition had been correct, then there should seem to us to be no more of an 'open question' concerning its truth than there is concerning the result of applying the definition to itself, that is, concerning the thesis that whatever we desire to desire we desire to desire.

As Moore's many critics have observed, this argument is problematic. It is not clear that definitions need to be obviously self-applicable in the way that Moore seems to assume (a point he later acknowledged in his discussions of the 'paradox of analysis'). His conclusion is also vulnerable to revisionists who offer an alternative, perhaps naturalistic, set of ethical concepts. These critics will argue that even if Moore is correct concerning the indefinablity of our concept of goodness, then so much the worse for our concept; we would do better to abandon it in favour of something less metaphysically demanding. Hence Moore's thesis can really only be made secure when it is embedded in a broader metaphysics which elucidates the nature of ethical concepts and explains thereby why they are indefinable. Moore himself offers a Platonist metaphysics of goodness as a simple, non-natural property whose a priori relationships to the natural properties of things we are able to discern through reflective ethical intuitions. Not surprisingly, few of his successors were able to accept this. As a result many of those who accepted his thesis that ethical concepts are indefinable held that the distinctive feature of ethical statements arises, not from any special ethical facts they purport to describe, but from the special role of these statements as expressions of emotion, or as recommendations and prescriptions (see Emotivism; Hare, R.M. §1; Prescriptivism).

This linguistic version of Moore's thesis is no longer popular because it does not appear to do justice to the content of ethical judgments. The reaction against it has not, however, led to a return to Moore's abstract conception of ethical values; instead it is Moore's anti-naturalist argument that is questioned, in particular his assumption that ethical naturalists have to offer a reductive definition of ethical value (see Naturalism in ethics §1). In this case, however, Moore might respond that his thesis (implicit in *Principia Ethica*, explicit in later writings) that the ethical value of a state of affairs supervenes upon its natural properties shows that this naturalist position cannot be correct (see Supervenience §1). For if ethical values are just simple natural properties, it is quite unclear why they should supervene on other natural properties. The ethical naturalist might well reply *ad hominem* that supervenience looks just as much a problem for Moore's conception of ethical value as a simple non-natural property. More deeply, however, the naturalist may want to claim that ethical values have an explanatory role within human psychology through their involvement in reasons for action which explains both their supervenience and their irreducibility. So at this point the debate about ethical naturalism connects with other debates about reductionism and naturalism in the philosophy of mind (see Reductionism in the philosophy of mind).

Although Moore's ethical theory is now primarily studied because of his critique of naturalism, at least two other aspects of it merit attention - his ideal utilitarianism and his emphasis on the value of art and love (see Utilitarianism). Moore's ideal utilitarianism owes much to another of his teachers, Henry Sidgwick, who had argued that utilitarianism, which he endorsed, involves two distinct doctrines: (1) the right action is that which makes the world as good as possible; (2) pleasure is the ultimate good. Moore agreed with Sidgwick on the first point (which is constitutive of ideal utilitarianism) but rejected the second, arguing that once we recognize that pleasure occurs within 'organic wholes' which include an affective response to perceived or anticipated states of affairs we can understand how there are evil as well as good pleasures (see Hedonism §1). None the less, Moore's own supreme goods, art and love, are themselves pleasures, so it is basically a refined hedonism that Moore himself commends; and it was certainly as such that his position was understood by his friends within the Bloomsbury Group (such as J.M. Keynes, Lytton Strachey and Leonard Woolf). Admittedly, in *Principia Ethica* itself Moore maintained that certain states of affairs not involving human consciousness possess intrinsic value; but in subsequent writings he affirmed the thesis, which became characteristic of the Bloomsbury Group, that it is only certain pleasant states of consciousness which have positive intrinsic value.

2 The rejection of idealism

Moore's criticisms of idealist ethical theory are accompanied by similar criticisms of idealist metaphysics (see Idealism). Moore directs his criticisms at three different idealist positions: he argues (1) that Berkeley's thesis that *esse* is *percipi* confuses the 'object' of perception with its 'content' (see Berkeley, G. §3); (2) that Kant's 'Copernican Revolution' wrongly treats a priori truths as if they were dependent upon the nature of human reason; and (3) that Bradley's 'Absolute Idealism' rests upon the assumption that all relations are internal, which itself only reflects confusions concerning identity and difference. For Moore these last two points connect closely with the distinction in whose terms the first is couched - that between the 'content' and 'object' of thought. His rejection of Kantian and Bradleian idealism is founded upon the thesis that the objects of thought are 'propositions', possible states of affairs which, in the case of a true proposition, actually obtain. The existence and truth of such propositions is altogether independent of our thought or knowledge of them; so there is no internal relation between the truth of a proposition and anyone's grasp of it, even in the case of a priori propositions.

Moore's initial reaction against idealist metaphysics led him to an extreme realist position concerning the existence of propositions and sensory objects, on the basis of which he held that traditional sceptical arguments could be easily rejected. But in his 1910-11 lectures *Some Main Problems of Philosophy* (1953) he recognized that matters cannot be quite so simple. He here abandons belief in the existence of propositions because he is no longer able to accept the existence of false ones (which, on his view, would be non-actual states of affairs). He also abandons his previous naïve realism concerning sensory objects, and takes the view that the objects of sense experience, which he here calls 'sense-data' (thereby introducing the term into the philosophy of perception), are non-physical representations of the physical world. And, having accepted this last point, he acknowledges that it is a good deal more difficult to find the fault in traditional sceptical arguments than he had previously supposed.

It is in discussion of these issues that Moore begins to develop two new methods of argument which combine to give his later writings their distinctive style - the appeal to common sense and the use of philosophical analysis.

3 A defence of common sense

Moore's appeal to common sense is not a dogmatic affirmation of the truth of the 'common-sense view of the world' in the face of critical or sceptical arguments to the contrary. Instead it belongs within a higher-order scepticism concerning the epistemic status of philosophical arguments themselves. Moore's claim is that the general principles upon which critical and sceptical philosophies rely are answerable to our everyday employment of the concepts they involve in our 'common-sense' judgments concerning particular matters of fact. Hence, Moore argues, critical and sceptical philosophers undermine the reasons for accepting the general principles on which they base their arguments. We are more certain that we know such things as that 'this is a pencil' than we can be of the premises of any sceptical argument which disputes such knowledge.

Moore's critics urge that this is too simple; after all, most sceptical arguments begin by exploiting entirely familiar grounds for doubt. And the status of 'common sense' is not itself unchallengeable; Moore, an agnostic, would not have welcomed an attempt to defend religious knowledge by an appeal to 'common-sense' religious convictions; but then he would have had to explain why common-sense beliefs about the physical world have an epistemic authority that simple religious convictions lack. In fact towards the end of his life Moore himself came to feel that more needed to be said in order to deal properly with sceptical arguments. Although in his famous lecture 'A Proof of an External World' (1939) he argued that, contrary to the claims of idealists, one could prove the existence of an external world by demonstrating the existence of one's hands, in his comments on this lecture Moore denied that one could prove in a similar way that one possessed *knowledge* of the existence of an external world. To do this one had to be able to refute sceptical arguments, and this could not be done by simply waving one's hands at them. Moore himself attempted this task of refutation in two of his very last papers, but in fact by the end of the second one he seems almost ready to concede defeat, while equally maintaining that scepticism about the external world is literally incredible.

4 Philosophical analysis

As Moore's 'A Defence of Common Sense' (1925) shows well, his appeal to common sense is typically combined with an emphasis on philosophical analysis. The background to Moore's conception of analysis lies in his early conception of a proposition as both the object of thought and a possible state of affairs. Thus conceived propositions are complex structures of objects and properties, and an analysis of their structure as objects of thought is equally a metaphysical account of the structure of reality. But Moore's conception of the role of analysis was greatly enhanced by his appreciation of Russell's work in logical theory, especially the theory of logical fictions (see Russell, B.A.W. §9). One issue to which Moore applied this theory was that of propositions themselves. For although he regularly represented himself as concerned with the analysis of propositions, he did not think that his talk of propositions had to be taken as carrying with it a commitment to the existence of propositions, as genuine entities to which reference is made in the analysis of propositional attitude idioms. But whether his treatment of this issue was altogether consistent can reasonably be doubted (see Propositional attitudes).

The context beyond all others to which Moore applied his conception of analysis was that of perception: he maintained that although there is no doubt concerning our *knowledge* of such propositions as 'This is a hand', their *analysis* is deeply puzzling. For Moore their analysis led directly into the philosophy of perception since he took it that the demonstrative 'This' refers here to a sense-datum, whose relationship to one's hand requires clarification through further analysis. Moore took it that there were three alternative positions here: (1) a direct realist position, according to which the sense-datum is part of the hand (for instance, part of its surface); (2) an indirect realist position, according to which the sense-datum is a non-physical representation of one's hand; (3) a phenomenalist position, according to which all talk of one's hand turns out, when fully analysed, to involve no more than descriptions of actual and possible sense-data (see Perception §2). Moore moved through different versions of these positions at different stages of his career without ever finding one that commanded his wholehearted assent, though in later writings he seems to have favoured the phenomenalist alternative. Moore's indecision is perhaps best regarded as a *reductio ad absurdum* of his initial assumption that demonstratives always refer to a sense-datum. For even though this assumption is intended to be compatible with direct realism, the fact that Moore assumes that there cannot be a failure of reference, even when there is no appropriate physical object to be demonstrated, shows that his conception of a sense-datum is that of an object of experience whose existence is

independent of the physical world.

Moore was always emphatic that he did not think that all the problems of philosophy could be resolved by means of philosophical analysis. He resisted the conception of logical analysis propounded by Wittgenstein in his *Tractatus Logico-Philosophicus* (1921) (even though he regarded the book, to which he gave the name by which it is now known, as a work of genius); and he was equally suspicious of Wittgenstein's later attempts to show that philosophical problems arise from a misunderstanding of our language. Yet there is no doubt that analysis did play a central role in Moore's philosophical thought: again and again in his writings, he approaches a question by offering an analysis of the propositions which enter into his initial formulation of it. One can best appreciate the role of such analyses by reflecting upon the fact that Moore was inclined to favour a phenomenalist analysis of propositions such as 'This is a hand' at the very time at which he was propounding his anti-idealist proof of an external world by demonstrating the existence of his hands to his audience. For this shows that Moore's appeal to common sense was more limited than is sometimes appreciated. According to Moore, we can employ this appeal to assure ourselves of the truth of such propositions as 'This is a hand'; but such an appeal tells us little about what their truth consists in. For this, we require an analysis of these propositions, and this can be as radically unfamiliar as one likes, as long as the truth values of our common-sense judgments are respected. Thus the apparent conservatism of Moore's defence of common sense is somewhat deceptive. To put the matter in Fregean terms, common sense constrains us to respect the reference of our ordinary judgments, but it does not thereby reveal their sense, whose elucidation rests instead upon the outcome of philosophical analysis.

For this reason, Moore is rightly regarded as a paradigm 'analytic philosopher'. Indeed his early writings played a crucial part in the development of analytic philosophy, since they implied that the analysis of the logical structure of propositions could be of direct metaphysical significance. But because Moore never subscribed to the broad metaphysical doctrines of logical atomism and logical positivism, his conception of philosophical analysis remained somewhat pragmatic, piecemeal and idiosyncratic. None the less, particularly because of his emphasis upon common sense, his work constitutes one of the essential elements within that broad conception of philosophy which we think of as 'analytic philosophy'.

Moral agents

Moral agents are those agents expected to meet the demands of morality. Not all agents are moral agents. Young children and animals, being capable of performing actions, may be agents in the way that stones, plants and cars are not. But though they are agents they are not automatically considered moral agents. For a moral agent must also be capable of conforming to at least some of the demands of morality.

This requirement can be interpreted in different ways. On the weakest interpretation it will suffice if the agent has the capacity to conform to some of the external requirements of morality. So if certain agents can obey moral laws such as 'Murder is wrong' or 'Stealing is wrong', then they are moral agents, even if they respond only to prudential reasons such as fear of punishment and even if they are incapable of acting for the sake of moral considerations. According to the strong version, the Kantian version, it is also essential that the agents should have the capacity to rise above their feelings and passions and act for the sake of the moral law. There is also a position in between which claims that it will suffice if the agent can perform the relevant act out of altruistic impulses. Other suggested conditions of moral agency are that agents should have: an enduring self with free will and an inner life; understanding of the relevant facts as well as moral understanding; and moral sentiments, such as capacity for remorse and concern for others.

Philosophers often disagree about which of these and other conditions are vital; the term moral agency is used with different degrees of stringency depending upon what one regards as its qualifying conditions. The Kantian sense is the most stringent. Since there are different senses of moral agency, answers to questions like 'Are collectives moral agents?' depend upon which sense is being used. From the Kantian standpoint, agents such as psychopaths, rational egoists, collectives and robots are at best only quasi-moral, for they do not fulfil some of the essential conditions of moral agency.

1 Agents versus recipients

Moral agents should be distinguished from moral recipients (see Moral standing). Moral agents are those who are morally accountable for at least some of their conduct. They are subject to moral duties and obligations, and, therefore, to moral praise and blame. Moral recipients are those who are owed moral consideration for their own sakes (see Respect for persons). On certain views moral agents and moral recipients are coextensive. Thus according to Kantians persons are the only moral agents and the only moral recipients (see Kant 1785). We should not be cruel to animals, not because animals are owed anything for their own sakes, but because cruelty to animals may indirectly harm persons who are the only ends in themselves (see Animals and ethics). According to utilitarians all sentient beings are owed consideration to the extent that they have feelings; so on this view there are moral recipients who are not moral agents - for instance, animals, or at least their feelings. Can there be moral agents who are not moral recipients? It would seem not, unless perhaps one uses moral agency in a weak sense which includes among moral agents nonsentient entities such as robots and corporations.

2 Understanding

The view that moral agents must have the capacity to conform to some of the external demands of morality is consistent with the view that there are parts of morality that they cannot conform to. Thus kleptomaniacs do not have the capacity to conform to certain moral requirements about not stealing, but it does not follow that they are not moral agents or that they should not be held morally responsible for murders that they might commit (see Responsibility). Moral agents must be morally responsible for some of their conduct, not necessarily for all. What, then, are the conditions of moral agency?

One essential condition is that the agent must have the relevant understanding (or capacity for understanding) of what the external requirements of morality are (see Moral knowledge §1). Thus in the case of murder one must understand that murder is wrong and that a particular act is an instance of murder. Exactly how much understanding is required is not easy to specify. There are plenty of borderline cases, but there are clear cases on both sides of the line. A baby does not have the relevant understanding of any of the requirements of morality, while an average adult citizen does at least sometimes. Of course even average citizens are very ignorant in many matters, but that at most is relevant to assessing their responsibility in these matters; it does not prevent them being

moral agents.

Some existentialist philosophers insist that moral agency requires the ability to create and choose one's own values, unconstrained by objective or rational considerations (see Existentialist ethics). It is objected that such creation involves a capricious freedom, since the agents have no guide as to how they should choose their values. Charles Taylor (1982) attempts to overcome this problem by suggesting that moral agency requires that one should have the capacity to choose one's values, after reflection, in accordance with one's deepest and most authentic nature (see Taylor, C. §§4-5). Does this requirement provide the necessary guidance for the agent? Critics would point out that this just shifts the problem. In what sense are we responsible for our deepest nature?

It seems that moral accountability requires that the agents should have an objective basis for choosing their moral values. They could then be held morally accountable to the extent that they have the capacity to find out what the relevant moral requirements are and, to the extent that they have the capacity, to conform to such requirements in the relevant ways. People who cannot reason properly (such as the severely mentally ill) or those who lack certain volitional abilities lack the capacity to conform to the relevant moral requirements.

In order to be morally accountable, an agent does not always have to know or even have the correct opinion about what the moral requirements are. The capacity for finding out such things can be enough. For instance, some Nazis who persecuted Jews may have thought sincerely that they were doing the right thing; but if they could and should have known better then they can be censured for moral negligence. Had they thought things through, which they could and should have done, they would have realized how wrong such acts were. Or so it is believed by those of us who want to hold them morally responsible.

To have the capacity to find out that something is morally wrong does not necessarily involve having the capacity to know why. It is plausible to distinguish having right opinions on moral matters from knowledge of them. The person who has knowledge in moral matters not only has the right opinions but also has them for the right reasons. Even after a study of moral philosophy many people do not know why things like stealing and murder are morally wrong; they do not understand the grounds for such judgments. True, theories have been advanced to answer such problems, but there is no general agreement on correct answers. An ideal moral agent, who exists only in the imagination of philosophers, might have knowledge of all moral matters, but ordinary moral agents have only opinions (for example, that stealing is wrong) and the capacity to find out such opinions in areas where they are held morally responsible.

According to some philosophers it is not enough to have the intellectual ability to tell right from wrong. There are psychopaths who are quite intelligent in general, and can even talk intelligently about morality. They might be able to tell us what things are wrong and even why, but they lack moral sentiments, such as remorse and consideration for others, and are unable to act for the sake of moral considerations. Many would say that they are not moral agents, and therefore not subject to moral condemnation, nor to punishment in so far as punishment presupposes moral condemnation. Bradley (1894) thought that psychopathic killers are not moral agents and so we cannot morally condemn them or punish them in the way we punish moral agents, but we have the right to use social surgery, even to kill them if that is necessary for social welfare, somewhat as we have a right to kill dangerous animals; considerations of justice do not apply to those who are not moral agents. Bradley forgot that considerations of humanity may still apply to them.

Bradley's view has been endorsed by Jeffrie Murphy (1972) but with two important qualifications. First, he points out that there is the danger of abuse in such a system. If we were permitted to go in for social surgery against nonmoral agents, moral agents might sometimes be wrongly diagnosed as nonmoral agents. Second, many people become psychopaths because of bad social conditions, and not of their own free will. Murphy rejects Aristotle's view that psychopathic wickedness is like a disease that people are responsible for acquiring by their voluntary conduct. He argues that psychopaths are those whose potential moral agency has been destroyed by society, and that they should therefore not be treated too harshly.

John Rawls (1971) maintains that only those who can give justice are owed justice (see Rawls, J.). And he stresses the importance for moral personality of acting from the sense of justice. On this view those who cannot act from a sense of justice would not be moral agents and so would not be owed duties of justice. But there is a weaker thesis according to which it will suffice to be owed justice if people can give justice even if they are not motivated by the

sense of justice. In the case of potential criminals, even if they are incapable of acting out of a sense of justice, or for the sake of moral considerations, we can apply considerations of justice to them and respect their rights if they respect the rights of others, even if their reasons for doing so are egoistic.

Indeed some Hobbesian philosophers contend that rational egoists can set up a just society, without the aid of a moral sense or a sense of justice (see Contractarianism §§2-3). Similarly, one could operate with a sense of moral agency, according to which agents have a capacity to conform to some of the external requirements of morality, but may lack the capacity to act for the sake of the moral law. They could sustain something like a morality. From a pragmatic point of view it would not matter too much why people conformed to moral requirements as long as they continued to do so. Jeremy Bentham (1817) thought that human beings were primarily egoistic, and that basic human nature was unalterable. He suggested that the setting up of the right institutions, such as representative democracy, and sanctions, such as punishment, would lead all members of the public, including the rulers, to see that contributing to the common good would be in their own best interests; thus rulers who acted against the public interest would be unlikely to be re-elected (see Bentham, J.). But would such rational egoists be moral agents? This is partly a verbal matter. They would satisfy the requirement that people should have the capacity to conform to some of the external requirements of morality, but they would not meet the Kantian requirement about being able to act for the sake of moral considerations.

3 The inner life and the Kantian view

The substantial question is whether the Kantian requirement is legitimate. Different moral theories give different answers to this question. Critics of the Kantian view might ask: if members of your family rescue you from a burning house, would you not think better of them if they did this out of affection for you rather than out of a sense of duty? Kantians would reply that if they did it out of affection, this would not at that time involve an exercise of their moral agency. This is consistent with the view that there may have been some exercise of moral agency in the past if the agent cultivated the right feelings and dispositions out of a sense of duty. Some people through good luck have better feelings and dispositions than others. Their qualities may even be wonderful, but do they deserve *moral* credit? Wittgenstein thought that G.E. Moore’s lack of vanity and his innocence generally might be loveable but Moore did not deserve any moral credit, for he was not ‘talking of the innocence a man has fought for, but of an innocence which comes from a natural absence of a temptation’ (see Malcolm 1966: 80). But what of the family members who fight against a selfish temptation to run away from the burning house where you are, and overcome it not out of a sense of duty but because of their love for you?

Persons who, through no fault of their own, have temptations to commit serious crimes are at a serious disadvantage compared to those of us who are lucky and do not have these temptations (see Moral luck). The former may deserve moral credit for conquering their temptations and for attempting to cultivate the right dispositions. Moral agency in one important sense of the term is to be contrasted with what happens as a result of luck. The conduct of individual agents is produced by a combination of factors: heredity, environment and free will. On the Kantian view, since personal choice is the only contribution to conduct made by agents themselves, it is only for this last factor that they are to be held morally accountable (see Free will).

The Kantian view of moral agency presupposes an enduring self that has the power of acting freely in a strong libertarian (or nondeterministic) sense. The enduring self on this view is different from an enduring character. The self is that which has the character and is autonomous in the sense that it has the power after reflection to change or not to change the character to some degree (see Autonomy, ethical). It is only to the extent that it has this power that it is held morally accountable for actions that issue from it or its character. If there is no enduring self, if the later self is a different self from the earlier one, then the later self cannot be morally accountable for the acts of its predecessor any more than a child can be for the deeds of its parents. Critics point out that the free will and the enduring self that are presupposed are incoherent. Either the character is determined by various factors that are ultimately outside the agent’s control or, if there is a break in the causal chain, then the act is a chance or random event and so again there can be no freedom.

Kantians reply that this objection loses force once we acknowledge the existence of the inner standpoint of the moral agent. C.A. Campbell (1957) has pointed out that from the internal standpoint we can make sense of a free act that is neither determined by factors outside our control nor a random event. Campbell appeals to our phenomenological experience of moral effort in the face of moral temptation, in which we can make sense of the

creative agency of the self, when the self has the power to go beyond its formed character. On this view what is really admirable about moral agents is that they can obey the moral law, rising above their feelings and passions by efforts of will made for the sake of the moral law. So the existence of the inner life is considered, at any rate on the Kantian view, to be another essential requirement of moral agency. It is this requirement that is not met by robots, corporations, states and other groups. Even if they instantiate rational systems or functional systems such that it makes sense to attribute actions (in a functionalist sense) to them, they do not have an irreducible inner phenomenology (see Functionalism). Thus a corporation or a state is not joyous and does not suffer (in the phenomenological sense) except in the sense that is reducible to the suffering and joys of its members. To say this is consistent with the view that such entities are extremely important in the influence they have over their members and that their behaviour and the laws governing them are not reducible to the behaviour and the laws governing the behaviour of their members.

William James (1907) pointed out that what gives significance to human life is that we can set ourselves ideals or goals and then pursue them with zest, overcoming obstacles in the way (see James, W. §3). If there were no struggle in human endeavour there would be nothing heroic about us. When we admire individuals for their struggle against temptation, or against disease, or their heroic attempt at conquering mountains or solving mathematical problems, we are appealing to an inner life. If a computer solves a mathematical problem, however ingenious its solution, there is nothing heroic about it.

It might be objected that one can understand the duty versus temptations battle without appealing to an inner life; one may give a dispositional analysis of temptation as well as of overcoming it. But Kantians would reply that we can only make sense of moral effort and free will if we assume an internal point of view. If we look at things from a purely objective point of view neither the presence of determinism nor its absence can make sense of our free will and of our moral agency.

4 Collectives and moral agency

There is sometimes disagreement about whether such categories as the insane, children, robots and collectives are moral agents. This disagreement can partly reflect different standards of moral agency being used. It can also be due to different views about the facts. Thus some of us may deny that robots are moral agents on the ground that they lack an inner life. Others may disagree with us on the grounds that an inner life is not essential to moral agency; and some may argue that even though an inner life is essential, robots of the sophisticated variety might be constructed in the future who have inner lives in the sense that human beings do.

People often wonder whether collectives such as nations, states and corporations are moral agents. On the assumption that they lack an irreducible inner life or that they lack a permanent or enduring self, they will not fulfil an essential condition for moral agency in the Kantian sense. But if we use moral agency in a weaker sense, then they too could be moral agents. Kantians would say that they are at best quasi-moral agents, but critics of the Kantian approach would complain that the Kantian view is too stringent; it has presuppositions that are unverifiable and controversial. Some of these critics prefer a practical solution where terms like free will and moral agency are used in a weaker sense.

On a Humean view people can be given moral praise if they meet the external requirement of morality by promoting social welfare, provided their conduct reflects their character (see Hume, D. §4). Similarly, they can be apportioned moral blame and punished if they produce social misery, provided their conduct stems from their character (rather than by accident). No permanent or enduring self in any deep sense is required. What is required is that the individual being blamed has the same character traits (in the relevant respects) as the one who committed the act. We are free to the extent that our conduct reflects our character. Deep problems like whether we are responsible for acquiring our characters are bypassed on this view. It implies that collectives too could be moral agents in the way that individual persons are.

Indeed Hume explicitly compared the person’s self to a republic or a commonwealth. So the argument that groups are less eligible for moral agency than individual human beings collapses on this view. Individual human beings can have character traits that persist; but so can groups. And though groups do not have an irreducible inner life, neither do individual human beings on the Humean view, according to which the ultimate constituents are the items of experience. The person does not persist over time in any deeper sense than groups do. The person’s

relation to the individual items of experience is like the relation of the republic to individual members who compose it (see Mind, bundle theory of). So on this view an individual can be morally accountable in much the same sense as collectives; this is one of the corollaries of his view that Hume did not notice.

Much communal violence presupposes ideas of collective moral agency. For instance, during the partition of India, when some Muslims in one part of the country persecuted Hindus, another group of Hindus would take retributive actions against some other Muslims in another part of India. The Hindus would often justify such conduct on the grounds that the people they attacked shared common characteristics with their coreligionists who committed the evil deeds elsewhere. The Muslims would use a similar justification against the Hindus and the vicious circle would continue. Jonathan Edwards (1758) thought that human beings are now morally accountable for the sins of Adam, for they belong to the same collective, humanity, and share the same fallen nature as Adam (see Edwards, J.). On the Kantian view (as well as on some other individualist views) this is not enough. Persons now are separate moral agents and have a separate centre of consciousness from Adam, even if they have similar character traits; the self is different from and transcends the character. Such requirements are often violated by those who mete out retribution at a collective level.

But we do seem to make moral demands upon collectives. Thus one might say that the IMF (International Monetary Fund) ought to provide more facilities for the poorer countries. And it has been claimed that some of these demands are not reducible to demands upon individuals. If this claim is correct, it would follow that at least a part of our moral language is addressed to those who are moral agents in the weak sense but not in the Kantian sense. This can also be seen in the case of young children, with whom we sometimes use moral language before they have become moral agents in the full Kantian sense. Indeed it is partly by participating in such use of language that children gradually acquire moral sentiments.

The Kantian sense of moral agency is presupposed only by parts of our moral system, especially that part which is concerned with apportioning moral desert from the point of view of cosmic fairness. If certain wrongdoers are not Kantian moral agents, the view that they deserve to suffer for their conduct is undermined. We do say to a child of two that it ought not to kill. We may even punish the child for its wrongs if that does some good; but we do not think that if it did not suffer for its wrongs in this life, it would be fair if there were another world, a hell, where it would be made to suffer, in the way that it would be fair if Stalin (assuming that he was a Kantian moral agent) were made to suffer in hell. As for the IMF, even God would not be able to send it to hell or make sense of its deserving to suffer (in the irreducible phenomenological sense) as a collective.

Moral development

The concept of moral development has its roots in Plato's metaphor of ascent from the dark recesses of the cave to the initially blinding sight of the form of the good. Influenced by the developmental theories of Jean Piaget, Lawrence Kohlberg proposed a sequence of stages beginning with two stages of egoism, followed by stages of conventionalism, contractarianism, consequentialism, and finally a Kantianism emphasizing the role of universalizable laws. Recent empirical work has not, however, corroborated moral stage theory. There seems not to be a unified mode of thought that applies to all and only moral problems.

In the 1920s, Jean Piaget articulated the idea that cognitive development in a number of domains (regarding, for example, substance, space, time) involved the development of progressively more adequate ways of thinking about each domain. Children's thinking could be classified according to Piaget in terms of unified modes of thought at each of four stages, in terms of what he called a 'genetic epistemology'. Like the Platonic picture of ascent (see Plato §14), stage progression involved progress towards seeing the nature of things more and more clearly.

In 1932 Piaget published *The Moral Judgment of the Child*, a book he called a 'preliminary piece of work', in which he presented two discoveries of note. First, young children, but not older children, judge the goodness or badness of actions more on outcomes than on motives: accidentally breaking a lamp is worse than intentionally breaking a less expensive object. Second, children initially think of prescriptive rules as unchangeable, and as originating outside human convention and social life; only later do they come to see rules as conventions designed for profitable human interaction and as adjustable accordingly. But, by the time a child is 10 or 11, rules are seen as emanating from humans engaged in complex social interactions, trying to harmonize interaction and avoid conflict. The rules are not so much forced upon us from the outside as are chosen by reasonable persons trying to engage in productive interaction. Adopting Kantian terminology, Piaget referred to this shift in the moral understanding of the child as a progression from a stage of 'heteronomy' to the stage of 'autonomy'.

Beginning in the 1950s, Kohlberg (1981, 1984) pursued Piaget's Kantian assumptions, claiming that individuals at the highest stage of moral development respond to moral problems 'in moral words such as duty or morally right and use them in a way implying universality, ideals, and impersonality'. In Kohlberg's hands, Piaget's two stages yielded to a six-stage scheme:

(1) egoism: right is what is rewarded and what is wrong is what is punished;
(2) instrumentalism: right is what serves one's needs and satisfies fair agreements;
(3) conventionalism: right is what conforms to age, gender, occupational and social role conventions;
(4) social contract: right is conceived in terms of the conventions of the society as a whole, especially the legal conventions;
(5) consequentialism: right is what promotes the general welfare even if this might involve breaking the law, for example, laws that discriminate on the basis of race or gender;
(6) Kant's 'categorical imperative': right is acting in accordance with rules that you would be willing to recognize as universal laws.

The descriptive sequence of moral stages follows a universal and irreversible sequence, and although not everyone reaches the highest stage of moral development, those who do will see the highest stage they reach as more adequate than the previous stages they occupied. Thus, a stage (5) consequentialist who is exposed to stage (6) Kantianism will judge it an improvement.

The empirical sequence of the stages, and the normative preferences of those occupying the stages, were thought by Kohlberg to increase the plausibility of the claim that the stages of moral development were in fact increasingly more adequate from a moral point of view. Although Kohlberg did not test the relationship between moral judgment and moral action, he explicitly assumed that there was a significant correlation between the two.

At the present time, moral stage theory is in a state of considerable disarray. Starting in the late 1970s, Carol Gilligan (1982) argued that Kohlberg's longitudinal study, based as it was on an all-male sample, was not listening to the ways women speak, and thus think, about moral problems. She claimed that males deliberate from a perspective that weights heavily respect for impersonal rules and rights, whereas females are more likely to find

the particular needs of others salient and to respond to moral problems out of direct care, concern and feeling for the other. Although Kohlberg claimed in only one co-authored paper to have found small gender differences between males and females, and generally concurred with finding of colleagues that there were none using his way of testing, Gilligan's critique opened the possibility of gender bias. Kohlberg was eventually forced to acknowledge that his was a theory of 'justice reasoning', but not of moral reasoning more generally (see Feminist ethics §1).

Gilligan's theory did not emerge unscathed, however, since subsequent analyses of male and female moral reasoning using a wide variety of testing procedures and types of problems show that the only significant gender difference has to do with the moral problems males and females think they face, but not with how they reason about different kinds of moral problems (Walker 1984).

Another problem for stage theory is the evidence of moral regression: people who at one time exhibit stage (6) Kantian reasoning may later endorse more conventionalist views. During the 1980s Kohlberg and his colleagues revised their scoring manual to eliminate regressors. However, in doing this they also unfortunately eliminated any confirmed cases of stage (6) justice reasoning.

Although the idea of moral development is still alive, the prospects of a unified moral stage theory seems dim. Moral philosophers and moral psychologists increasingly agree that the domain of morality contains heterogeneous types of moral problems and responsiveness to different types of problems may well require different special-purpose competencies, or 'virtues', not some general 'moral faculty'.

Moral education

This entry looks at three contemporary approaches to moral learning and education, all of which have roots in the history of philosophy. The first holds that just as children grow, or develop, in a physical sense, so they also develop in their moral dispositions or judgments. A central issue here is whether the concept of development is applicable outside its biological home.

The second sees moral learning not as a natural process, but as a deliberate induction into socially approved norms or values. On one version of this view, it is not enough to bring children to follow the rules enshrined in conventional moral codes as they need to learn to sift these in the light of higher-order rational principles. Problems arise here both about moral motivation and about whether morality is wholly to do with rules and principles. For other theorists moral education is more a matter of shaping children's nature-given desires and emotions into settled dispositions or virtues on Aristotelian lines. While the 'rational principle' view focuses on the morally autonomous individual, this view has its roots in communal moral traditions.

Despite Plato's belief that only knowledge is teachable, and therefore that it is doubtful whether moral goodness can be taught at all, the third view of moral learning maintains that it must include the acquisition of relevant knowledge and understanding, and cover the formation of dispositions. All this bears on how moral education should feature in schools - on the role of school ethos, learning by example, and the contribution of the whole curriculum.

1 Moral development

Let us start with a biological approach to moral growth in children. On this view morality develops in us from within, given appropriate external circumstances, from innate seed through to maturity. Rousseau's *Émile* (1762) has been a key text here for modern developmentalists, although few have followed his specific suggestion that the moral sentiments appear only with adolescence (see Rousseau, J.-J. §4). Jean Piaget charted the development of moral judgment (as distinct from moral behaviour) in children, identifying three main stages through which they pass: from a pre-moral lack of awareness of moral rules, via a perception of them as sacrosanct, to a more reflective understanding of their point in fostering cooperation and mutual flourishing. Subsequent psychological investigations by Lawrence Kohlberg (1981) of children's moral judgments, as revealed in their responses to stories involving moral dilemmas, told a broadly similar story (see Moral development).

Developmentalist accounts have appealed to that brand of 'child-centred' educator wary of attempts to mould or indoctrinate children into socially approved codes and attitudes and eager to leave as much as possible to children's own resources. They have not been without their critics. Carol Gilligan (1982) has drawn attention to the fact that Kohlberg's subjects were all boys; when girls' judgments were studied, their responses showed less evidence of detached appeal to principles and more of a caring response to particular individuals' needs and desires. While Gilligan's work has been important in psychology in pointing to gender differences in moral learning, it also raises the philosophical questions of what is meant by 'moral maturity' and how this is to be identified (see Feminist ethics §1). The claim that the morally highest state is consciously to be guided by abstract principles might be accepted by philosophers of a Kantian persuasion, but others might disagree (see Universalism in ethics §3).

On one view, the notion of moral development, if taken strictly, is incoherent. This view sees moral learning as a matter of being shaped in certain desired directions by one's parents, teachers and perhaps social influences more generally. It rejects the atomic individualism implicit in the developmental model, where social phenomena are at best environmental influences nurturing moral growth rather than intrinsic features of human personhood (see Human nature §2).

2 Moral education: the place of rules and principles

An uncomplicated notion of moral education favoured by some governments, religious bodies and no-nonsense members of the public identifies it as bringing children's behaviour into line with moral rules to do with such things as telling the truth, refraining from physical harm, and keeping one's promises. In especially uncomplicated versions, these rules are 'moral absolutes', allowing of no exceptions.

Many philosophers have argued that moral education must go further than mere rule-following. For one thing, the view of what is morally wrong - that masturbation is sinful, for instance - might itself be baseless. Moral education must help young people critically to assess the acceptability of these and other rules, otherwise it may degenerate into indoctrination. Moral autonomy is the central aim: indeed, as long as pupils are 'blind' rule-followers, they cannot strictly be said to be acting morally at all, but at best sub-morally (see Autonomy, ethical; Moral agents). This position is clearly akin to Piaget's and Kohlberg's, except that acting according to moral principles is not the end point of a developmental process, but the product of conscious social direction. As to how the moral principles should be characterized, philosophers of education have held different views. While some have been attracted by utilitarianism, others have been more Kantian (see Utilitarianism; Kantian ethics). The latter group include the early R.M. Hare (1952), despite his un-Kantian insistence on individual 'decisions of principle', and Peters (1981), who would replace Kant's monistic emphasis on the categorical imperative with a broader array of 'transcendentally deduced' ultimate principles, such as impartiality, benevolence, truth-telling and liberty.

Critics of this general approach have pointed to weaknesses in its central demand that moral beliefs be based on higher-order principles. Given the disagreements just mentioned about their content and capability of rational justification, what happens if the learners, encouraged to find an incontrovertible, rational basis for their moral beliefs, fail to find one? Moral autonomists are only a hair's-breadth away from moral sceptics: if there is, after all, no good reason for being moral, why strive to be so (see Moral scepticism; Moral justification §3)?

The question is as old as Plato, whose rationalist approach to moral education has contemporary echoes in the view under discussion. Plato's *Republic* is partly an answer to Thrasymachus' question at the outset asking why it is in his interests to be just. The account of the education of the guardians later in the work shows them learning to base their conduct not on taken-for-granted orthodoxy, but on the sure foundations of knowledge of the Good. Whether Plato's arguments here and elsewhere in the *Republic* succeed in answering Thrasymachus is disputable, as is also his assumption that if the guardians attain a proper knowledge of the Good, this is enough to guarantee their acting well (see Plato §14). Contemporary rationalists tend to rate moral knowledge a necessary, rather than a sufficient, condition of moral learning, for in addition children have to acquire appropriate dispositions to bring their behaviour into line with what they know to be right (see Moral knowledge §§1-2; Moral motivation §§1-2). Like Plato, however, their whole account is vulnerable if its foundations prove shaky.

This approach to moral education has also come under fire for the narrowness of its conception of morality. In concentrating so heavily on the rules and principles that one morally ought to follow, it does less than justice to other features of the ethical life, especially the virtues (see Virtues and vices §§1-3). True, it puts weight on intellectual virtues like clarity and independence of thought, as these will be necessary when one makes the abstraction to moral principles; true, too, that the names of proposed principles, like benevolence or impartiality, are also names of moral virtues; and that the great weight put on getting learners to see what they morally ought to do and act accordingly may be said to imply a master virtue of moral conscientiousness. But what can the theory say about children's learning to be courageous, kind, self-controlled, moderate in their bodily appetites, friendly, generous, cooperative, confident, or equipped with a proper measure of self-esteem? Even where benevolence comes into the rationalist account, as in Peters, it presupposes learners who finally come to act benevolently because this is what they morally ought to do, and not out of some more spontaneous fellow-feeling for the other. We come back to Gilligan's difficulty with Kohlberg, as well as, more broadly, to the question of the relative roles of reason and emotion in moral motivation (see Morality and emotions).

3 Moral education: the place of virtues and community

Children need to learn how to regulate their feelings of anger when frustrated, as well as their bodily appetites for food, drink and in due course sex. Contemporary approaches to moral education influenced by Aristotle (for example, Carr 1991) start, as his does in *Nicomachean Ethics*, with biological features of human nature such as emotions and physical desires like these and see the educator's task as helping to shape them in desirable directions (see Aristotle §22). Acquiring the virtue of self-control, for instance, is a matter of learning such things as when to feel anger or express it in appropriate behaviour, to what degree, on what occasions, and towards which people (see Self-control).

Similar points could be made about the bodily appetites in relation to the virtue of moderation, fear in relation to

courage, our inbuilt reactions to others as social animals in relation to virtues like friendliness or generosity. In each case children need habituation in responses fitting the particular occasion. These cannot be subsumed under rules as they require flexible and intelligent adjustment to circumstances (see Virtue ethics).

On such an account, moral education starts by getting children to behave in the way which a virtue would require in different particular situations. At first, they can have little or no understanding of why they have to do this, but they gradually learn to make the flexible responses just mentioned and thereby come to see what they feel and do under the aspect of, say, the courageous or the considerate, rather than, more primitively, as eliciting pleasure or preventing pain. Rationality is already at work in the shape of the practical *nous* which generates the flexible responses. It comes in, too, at a deeper level as children begin to grasp how self-control, generosity and the other virtues fit together in a wider picture of their wellbeing, Aristotle's *eudaimonia* (see Eudaimonia). For Aristotle, indeed, practical wisdom is the master virtue, embedded in the other virtues, but also helping us, against a larger canvas, to lead a flourishing life overall. It presupposes a theoretical understanding of whatever material is necessary for our appropriate responses. One contemporary illustration: in coming to terms with their sexual desires and knowing what to do when, young people these days have to have some knowledge of biological functions, contraception, AIDS, and their own and others' psychology.

On this view rationality has to do not with subsumption of actions under rules and rules under principles, but with relating particular responses to more global pictures of one's wellbeing (see Virtue ethics §6). The latter, in Aristotle, is inextricable from the flourishing of wider groups. While the rationalist account of moral education focuses on individuals and what they morally ought to do, the Aristotelian starting point is the ethical life of a political community (see Community and communitarianism). Learners learn the subtleties of what to do and feel within not fully articulated traditions of response embedded in their family and broader communal life (see Family, ethics and the §6). In addition, the virtues they acquire - courage, temperance, justice and others - are necessary not only for their own flourishing, but also for that of those around them.

There are differences of opinion about how far this Aristotelian approach is applicable to moral education not only in the Greek city state, but also in societies of scores or hundreds of millions of people like the political units in which we live today. Has the tradition of virtues-education been eroded irreparably except within favoured religious and other communities not destroyed by the ravages of modernism, as Alasdair MacIntyre has suggested?

Two other issues remain. First, could virtues-education be the whole of moral education? Should it be combined with elements of a rules-and-principles approach? And are there actions which do not feature in children's moral upbringing as such, but belong beyond the pale, in the realm of the unthinkable - perhaps things like murder, physical harm, or theft? Second, should children be brought up, as in the Aristotelian tradition, to see their own flourishing as inextricable from that of others? Or is 'morality' to be kept apart from 'prudence' (see Prudence)? If the former, is there still any place for moral education as a distinguishable part of education?

What seems clear is that there is a great diversity of ethical values jostling for a place in children's upbringing - Aristotelian virtues, utilitarian considerations, Kantian values of impartiality, autonomy and respect for persons, role-obligations, beyond-the-pale prohibitions, commitments to one's personal projects, and more besides. If these, or most of these, are to be included, are children to be taught to arrange them, in the rationalist mode, in some kind of systematic hierarchy of importance? Or are they to be encouraged, more after the Aristotelian pattern, to resolve conflicts intelligently within and between irreducible values in the light of specific circumstances (see Examples in ethics §2)?

4 Procedures of moral education

Plato first raised the question in the *Protagoras* whether morality - including the virtues of good citizenship - can be taught. Socrates doubted this on the grounds that there are no specialist teachers in this area as there are in, say, architecture or naval design (see Socrates §2). Socrates was assuming that teaching is a matter of transmitting knowledge. On this assumption, there is indeed a problem - despite Plato's later position in the *Republic*, described above - since the acquisition of knowledge, either propositional knowledge or skills, is no proof against wickedness. Children need to become good, not merely to know about the good. Hence the vital importance of cultivating desirable dispositions in them - which may count as teaching morality on a broader definition of 'teaching' than Socrates'. As a part of this enterprise the narrower kind of teaching of empirical knowledge is

important, too, as the example of sex education shows, but only as an adjutant to the dispositions. Some moral educators would also put weight on giving children - perhaps even younger children - a more philosophical understanding of the nature of moral issues; but not all would agree with this.

As to how the dispositions and their attendant knowledge - of whatever sort - are best acquired, answers will differ according to the emphasis one puts on a communal starting point for morality and to one's views on the separability of morality from personal wellbeing. Most writers on the topic stress learning by example. As for school learning in particular, some would start with the educative ethos of the whole institution, others with classroom activities. For some, like Dewey (1909) for instance, moral education is not a separate subject, but should pervade every aspect of the life of the school community, while for others it is closely allied to religious education. For an Aristotelian the teaching of literature could be especially important in revealing conflicts of ethical value and subtleties of judgment (see Examples in ethics §3).

Moral expertise

Moral experts are best defined as those who have studied moral questions carefully, know the main theories developed in response to such questions, and (where possible) know and are able to offer arguments that would convince reasonable people.

In scientific and technical areas, one important feature of a successful answer is that it works, in the sense that it makes accurate predictions. We can say that successful answers to moral questions take the form of arguments which, if examined carefully, would persuade reasonable people and lead to convergence in their moral views.

The moral responsibility of individuals for themselves does not preclude the role of moral advisor. Many self-pronounced moral experts might be interfering, condescending and hypocritical, but such characteristics need not accompany moral expertise. Probably no one could claim a high degree of expertise in all areas of ethics.

1 Attempts at a definition

Moral expertise certainly involves more than merely knowing what moral views are prevalent within a profession or a society (see Morality and ethics §2). There are people who study different professions' 'codes of ethical practice' (see Professional ethics). There are social scientists who study and know a lot about the moral views prevalent in one or more societies. Are such people moral experts? Only the most extreme form of moral relativist will think that these people must be moral experts. The crucial question here is whether to know what a given group's moral views are is necessarily to know what actions or practices would really be morally right. Extreme moral relativism seems implausible. The moral views prevalent in some groups certainly seem morally worse than those prevalent in other groups (see Moral relativism). Moral expertise presumably involves some ability to sort the better from the worse moral views.

We might go further and say that, if there is a distinction between better and worse moral views, then the people with the best moral views could qualify as moral experts. However, if what makes certain people moral experts is that their moral views are best, then in order to determine who the moral experts are we would first have to determine which moral views are best. Yet once we find out for ourselves which moral views are best, why do we need the notion of moral experts? If we make having the best moral views the criterion for moral expertise, it is unclear what role moral expertise has left to play.

We could try the view that experts are those who have studied the relevant questions and problems and who know the competing theories about them and whatever evidence there is. We do not have to know which controversial view in physics is right to know who the experts in physics are. Likewise, we might think of experts in some area of morality (such as business ethics or medical ethics) as those who have studied the area's moral problems, considered the opposing moral arguments, and even tested their own arguments and principles on informed audiences. The experts are sometimes proved wrong about what the correct view is, but they are the ones to whom we would reasonably go for help.

2 Moral expertise and scientific expertise

The comparison between morality and science immediately raises the question of whether a difference between them makes the idea of expertise appropriate in science but not in morality. There is broad agreement that one important feature of successful answers to scientific questions is that they make predictions that turn out to be correct. In applied sciences like medicine and mechanics, a successful answer is the one that cures the patient or makes the machine do what we want. We can then say that an expert in such fields is someone who regularly returns answers that are successful in that they achieve some agreed upon aim. So the question will be whether in ethics there is an agreed upon aim that would specify what would count as successful answers to moral questions.

Some would say that the agreed upon aim is to find ways of living and behaving that reasonable people would accept as justified. Just as an expert in medicine might be expected to give advice which, if followed, would maximize our chances of a long life, a moral expert might be expected to provide arguments which, if examined carefully, would persuade reasonable people and produce convergence in their moral views.

The criterion of success in moral arguments cannot be mere success in convincing people (after all, sophistry can

be good at convincing people). Rather, the arguments must be ones whose careful examination would resolve moral disagreements. What counts as careful examination? Certainly, the arguments must be ones that would stand up to logical scrutiny. They must also be arguments whose premises and conclusions would still seem compelling after people with powerful imaginations teased out all the implications.

We should not go so far as to claim that no one can have moral expertise unless they can present moral arguments that will persuade everyone who is reasonable and considers the arguments carefully. In other disciplines, there can be expertise without convergence of opinion, so why not in ethics? But where there are arguments whose careful consideration would persuade every reasonable person, then those who can mount these arguments have greater moral expertise in this respect than those who cannot.

The stress on good arguments in ethics suggests another difference from science, especially from applied natural science. With scientific questions, we sometimes might merely want the answer that works and not really be interested in the background theories and evidence that support the answer. In ethics, however, asking for the answer to a moral question without wanting to know the reasoning behind it looks like an attempt to duck responsibility.

3 Some concerns about moral expertise

What is the point of looking for moral experts if each of us must take responsibility for the morality of our own actions and way of life? That we must take responsibility for the morality of our own actions and way of life does not preclude a role for moral advisors. Indeed, when we face difficult moral decisions, consulting judicious advisors might often be the responsible thing to do.

Nevertheless, in mainstream Western culture to call someone a moral expert would seem ironic. It would typically be thought to suggest that the person is judgmental, interfering, condescending, self-important, hypocritical and perhaps close-minded about morality. Self-righteousness is almost never attractive. But moral expertise does not inevitably lead to an unpleasant personality. On the contrary, honesty will require those with moral expertise to acknowledge their own moral mistakes and fallibility.

It will also require them to acknowledge their limitations. Few could plausibly claim a high degree of moral expertise in all of many different areas. Think how much time and energy it would take to study in depth (even just most of) the problems and theories in the ethics of medicine, business, law and government, not to mention military ethics, ethics in international affairs, academic ethics, and the ethics of personal relationships. Although there may be some features common to problems in all these areas, there are also morally relevant differences between them. So expertise in one such area does not carry over into expertise in another. Part of having an expertise can be knowing its limits.

But Williams goes on to explain how there is a place for the idea

of a helpful advisor on whether a particular ‘thick ethical concept’ (such as ‘treacherous’, ‘kind’, ‘honest’) applies in a given case.)

Moral judgment

The term 'moral judgment' can refer to four distinguishable things. First, the activity of thinking about whether a given object of moral assessment (be it an action, person, institution or state of affairs) has a particular moral attribute, either general (such as rightness or badness) or specific (insensitivity, integrity). Second, the state that can result from this activity: the state of judging that the object has the attribute. Third, the content of that state: what is judged by us, rather than our judging it. And fourth, the term can be read as commendatory, referring to a moral virtue that we might also call 'moral discernment' or 'moral wisdom'. There are three principal questions regarding moral judgment. The first asks what kind of state the state of moral judgment is, and in particular whether this state is to be characterized, either wholly or in part, as a state of belief. The second is concerned with the activity of moral judgment, investigating especially the role within this activity that is played by the application of rules. The third examines the conditions under which a person is justified in making a moral judgment with a given content.

1 Cognitivism versus noncognitivism

When I think that something has a certain moral attribute (that an action is wrong, say), the state I am in seems to have features both of cognitive (belief-based) and noncognitive states (see Analytic ethics §1). First, my moral attributions aspire to objective truth - to being true independently of my attitude towards them. For my moral attitudes can take the form 'This action is wrong, and would have been wrong even if I had approved of it', committing me to moral facts of the matter that I can be right or wrong about (see Moral realism §1). And a state that aims to be true to independently obtaining facts must be thought of as a belief, it seems (see Belief). However, attributing a moral or any other evaluative feature to something seems to go beyond being in a merely cognitive state: it seems to involve orienting myself towards or away from the object of the attribution. In particular, it is often maintained that there is a certain sort of 'internal connection' between the state of moral judgment and the judge's motivation: it is part of the concept of judging something to be wrong that if I judge that it is wrong to perform this action in these circumstances, then (provided I am not weak-willed, and other things equal) I am motivated to avoid it in these circumstances (see Moral motivation §§1-2).

Thus cognitivism about the state of moral judgment - the view that it consists essentially in a belief - seems to be supported by its objectivity-presupposing character, while noncognitivism (the denial of cognitivism) seems to be supported by the internal connection to motivation. The problem is not simply resolved by characterizing moral judgment as a compound state, comprising both a belief and a noncognitive companion state. For this would seem to require as an isolable component a pure belief that the action is wrong, and the possibility of such a belief is precisely what is at issue.

Beyond this, four main options present themselves. Each side of the dispute can either deny the claim being adduced in support of the other, or accept the claim while denying the relationship of support. Thus, first, a cognitivist might deny the internal connection, insisting that to the (unsurprisingly widespread) extent that moral judges tend to care about morality, this is only contingently true. A second, less plausible view is a noncognitivism that simply denies that moral judgments presuppose objectivity. Perhaps, as emotivism suggests, objectivity-presupposing moral judgments ought to be rejected and replaced with something else (see Emotivism); it seems hard to deny that moral judgment as it actually exists does have this objectivity-presupposing character. This leaves two possibilities, each of which attempts to allow for both the objectivity-presupposing nature of moral judgment and its internal connection to motivation. According to the cognitivist internalism of John McDowell (1979), moral judgments are indeed beliefs, but beliefs of a special kind, in being internally connected to the believer's motivational states. And according to the noncognitivist objectivism of Simon Blackburn (1984) and Allan Gibbard (1990), the objectivity-presupposing character of moral judgments can be explained without construing them as beliefs. The central thought here is that the attitude expressed by 'This action is wrong, and would have been wrong even if I had approved of it' can be explained as a noncognitive attitude that ranges across counterfactual as well as actual possibilities - as an attitude of approval of the action not only in the world as it is, but in the world as it would have been if I had happened to approve of the action but the world were otherwise unchanged.

It remains unclear, however, whether noncognitivism can supply a satisfactory treatment of the full range of semantic features of moral judgment-contents, and in particular, of unendorsed occurrences of moral terms, such as the first occurrence of ‘wrong’ in ‘If blasphemy is very seriously wrong, then it is wrong to associate with blasphemers’ (see Analytic ethics §2). If not, we should be cognitivists about our actual states of moral judgment. Whether sense can be made of the objective moral facts seemingly presupposed by moral judgment is a further question - the question of moral realism (see Moral realism).

2 Moral rules and deliberation

What is the role of rule-application in good deliberation about the moral attributes of things? A widespread view is this: good moral thinking identifies correct moral principles under which the moral judge then subsumes particular instances to produce a moral verdict about them (see Logic of ethical discourse §6; Universalism in ethics §3).

On this view, though, not much actual moral deliberation can qualify as good. Few moral judges are equipped with an exhaustive set of exceptionless moral principles by reference to which all their moral judgments are made. Most of the time, when we deliberate about whether a case instantiates a moral concept, we are engaged in an activity of moral discernment or judgment that is not simply a matter of applying a fully determinative, independently articulable rule to the case. Moreover, there seem to be good reasons not to conceive of moral deliberation as consisting ideally in the application of an exhaustive set of exceptionless moral rules. This view confronts a dilemma. Either our set of principles would be small and readily comprehensible - perhaps consisting of a single member, as in direct utilitarianism (see Utilitarianism) - but would need to be framed in such general terms as to make their application to even the simplest cases a difficult matter to determine; or they would be framed in terms specific enough to make the assessment of their application to particular circumstances straightforward, but would thereby need to be so numerous and highly qualified as to be unusable.

This does not yet show that good deliberation cannot consist solely in the application of rules, however. On R.M. Hare’s consequentialist view (1981), the response to this problem should be to equip ourselves with a set of familiar moral rules of thumb (for instance, ‘Promise-breaking is wrong, other things being equal’), together with a meta-rule that in cases where these rules conflict we should apply a fundamental principle of direct consequentialism (see Consequentialism; Hare, R.M.). Alternatively, Barbara Herman’s Kantian theory (1985) tells us to equip ourselves with an equally familiar set of rules of moral salience - rules identifying certain features of the maxims on which actions are performed as those showing that the actions bear the burden of moral justification - together with a meta-rule that, when an action has a morally salient feature, its permissibility is to be judged in terms of the fundamental categorical imperative principle (see Kantian ethics).

3 Moral rules and justification

The views just described allow that it is proper for much of our deliberation to proceed by appealing to merely *prima facie* rules - rules specifying defeasible reasons (reasons capable of being outweighed) for making a moral attribution - but they supplement them with more fundamental, fully determinative rules governing judgment in cases where the *prima facie* rules conflict. But why should we seek rules of the fully determinative kind? The natural answer is this: good moral deliberation issues in judgments that are justified; if an all-things-considered judgment I make, in a case where my *prima facie* rules conflict, is to be justified, it cannot be arbitrary; and a judgment of mine can only be non-arbitrary if it instantiates a fully determinative rule.

When it is said that judgments are only justified by the existence of rules, two things might be intended:

(a) What makes it right to apply this concept to this object is a rule for doing so.
(b) What warrants me in judging that this concept applies to this object is a rule for doing so.

Claim (a), we might say, concerns the ‘constitutive justification’ of a judgment-content, whereas (b) concerns the epistemic justification of a state of judging (see Justification, epistemic).

Claim (a) pictures constitutive justification as consisting in the subsuming of instances under rules. This picture has been attacked, on the ground that it betrays a fallacy about rule-following (see Wittgenstein, L.J.J. §10; Meaning and rule-following). Our ability to discern whether a given case falls under a rule cannot consist in our grasp of an independent meta-rule, on pain of regress. This applies to the rule ‘Identify instances falling under

concept *c*’ as much as to any other. Proceeding correctly in the application of a concept cannot require sensitivity to an independently articulable rule which one’s practice of applying the concept follows. If so, then this leaves open the possibility that there are no such further rules that justify our practice of moral concept-application. The onus is on a proponent of such rules to produce compelling examples that do square with our practice; the criticism is that they have failed to do so.

According to opponents of (a), then, there is no obstacle to the claim of ‘moral pluralists’ that the only defensible moral rules are *prima facie* ones (see Moral pluralism). A further claim is that there are not even rules of this limited kind. This is held by moral ‘particularists’, who claim that there are no properties that always count as reasons for the same moral attribution. Often, the fact that an action of mine will harm someone is a reason for the wrongness of the action; but sometimes (for instance, if I am rightly administering a just punishment), it will count morally as a reason for its rightness (see Logic of ethical discourse §6). If so, we need to exercise a form of moral judgment that goes beyond the application of rules not only in order to determine how moral reasons relate to each other, but to determine when a consideration counts as a moral reason (see Virtue ethics §6)

4 The virtue of moral judgment and moral epistemology

If claim (a), with its subsumptive picture of constitutive moral justification, ought to be rejected, then so should (b), concerning epistemic justification. If there need be no independently articulable rule for a correct moral attribution, then there need be no such rule for my being warranted in judging that the attribution is correct. This still leaves it open to claim a relation of mutual epistemic support between my judgments concerning *prima facie* moral principles and my judgments concerning the existence of moral reasons on particular occasions, given a coherence conception of epistemic justification (see Knowledge and justification, coherence theory of). However, concerning the justification of my judging that, all things considered, a particular object has a given moral attribute, it seems that we must say simply that this is justified provided it is the attribution that would be made by a person with the virtue of moral judgment or discernment.

How can one ever be warranted in believing this? If the correctness of a moral judgment depends on its endorsement by an agent with a virtue the conditions for the possession of which are not independently specifiable, then it seems that any claims to epistemic justification will amount to dubious claims of self-evidence (see Intuitionism in ethics). To progress beyond this, we should need to be able to cite the convergence in judgment of those whom we have independent reason to identify as good moral judges (see Moral expertise).

Moral justification

Questions of justification arise in moral philosophy in at least three ways. The first concerns the way in which particular moral claims, such as claims about right and wrong, can be shown to be correct. Virtually every moral theory offers its own account of moral justification in this sense, and these accounts naturally differ from each other. A second question is about the justification of morality as a whole - about how to answer the question, 'Why be moral?' Philosophers have disagreed about this, and about whether an answer is even possible. Finally, some philosophers have claimed that justification of our actions to others is a central aim of moral thinking. They maintain that this aim provides answers to the other two questions of justification by explaining the reasons we have to be moral and the particular form that justification takes within moral argument.

1 Three questions of justification

Questions of justification arise in moral philosophy in at least three different ways. First, it is generally taken as a central task of moral philosophy to clarify the structure of first-order moral thinking. A theory should, for example, explain 'what makes acts right'(see Morality and ethics §1). Is the status of an action as morally right or wrong determined by its actual or expected consequences, by its conformity to certain rules or standards, or in some other way (see Consequentialism; Deontological ethics)? Any theory that answers these questions provides us with an account of moral justification, that is to say, of justification *within* morality.

A second task of moral philosophy is to explain why we should care about morality and give its requirements priority over other considerations. This can be seen as a matter of providing a justification of morality.

Third, some philosophers have argued that it is a central aim of morality (or of some part of it, such as principles of justice) to provide a basis for justifying our actions or our institutions to one another, and that this aim provides a basis for understanding the importance of morality and for determining its content. According to these writers, justification is an aim of morality.

2 Justification within morality

Every moral theory offers its own account of moral justification. There is, however, a more general methodological question that transcends particular accounts of 'what makes acts right', namely the question of how the claim of any such account to be the correct account of moral justification can itself be justified.

One answer to this general methodological question has been formulated by Rawls (1971) as the method of 'reflective equilibrium' (see Rawls, J.). According to this method, one begins by identifying one's 'considered moral judgments', those judgments in which one has the highest degree of initial confidence. These may be judgments of any degree of abstraction: judgments about the rightness or wrongness of particular actions, about the correctness of general moral principles, or about the moral relevance of various considerations. One then tries to find the set of principles (the account of the particular area of morality in question) that best fits with these judgments. This fit will almost certainly be imperfect, so one then proceeds to consider whether and how to modify the principles one has formulated to yield a better fit with one's considered judgments, and whether and how to modify these judgments in the light of the principles at which one has arrived. This process of revision leads to a new set of principles, and hence to a new stage of adjustments of principles and judgments. The process continues until 'equilibrium' between principles and judgments is reached; the principles one has formulated at that stage are to be taken as justified as an account of the area of morality in question.

This account of how moral principles are to be justified has been attacked, chiefly on the ground that it gives too much authority to the considered judgments with which the process begins. This is sometimes put in the form of a charge that it is circular to base an argument for a particular form of moral justification on some of the very beliefs that are to be justified. It is also objected that two people, using this same method, might arrive at quite different principles, because they began with a high degree of confidence in different sets of judgments. In reply, it can be said that the charge of circularity is misplaced, since the aim of the process is not to supply a needed justification for every moral belief we have, but rather to come up with the best general account of the subject matter. How else could we arrive at justified conclusions about a subject except by relying, at the outset, on those beliefs about that subject that seem to us most likely to be true? Moreover, in the search for reflective equilibrium no particular

judgment is assumed, irrevocably, to be correct. Any reasons we might have for mistrusting particular beliefs are taken account of in the process as described, either as possible reasons for denying them the status of considered judgments to begin with or as reasons for abandoning them later when their incompatibility with the best account of our other beliefs comes to light.

3 Justification of morality

Turning now to the question of justifying morality itself, circularity looms when the bases of a proposed justification seem themselves to be moral in character. One cannot answer the question ‘Why care about right and wrong?’ by saying that it would be morally deficient not to. There is a dilemma here, however, since a justification for morality that appeals ultimately to values that are clearly not moral (such as those of self-interest) does not seem to give the right kind of explanation of morality’s importance. It does not seem that virtuous people care about what is morally right because doing so is conducive to their self-interest.

Prichard (1917) concluded from this dilemma that moral philosophy, or at least that part of it that seeks to provide a justification of morality, ‘rests on a mistake’ (see Prichard, H.A. §2). A less pessimistic conclusion would be that an adequate justification, or explanation, of the authority of moral requirements must appeal ultimately to considerations which are evidently relevant to morality yet have a significance which is not wholly dependent on it. The appeal of utilitarianism for some people, and the conviction of others that morality must have a basis in religion, can be explained in part by the fact that the ideas of the greatest happiness of the greatest number and of divine will appear, to members of these groups, to be the only plausible solutions to this problem. That is to say, these reasons have seemed to represent values both relevant to morality and able to supply it with the proper authority, but not (so it is claimed) dependent on it. One question is whether there are other kinds of reasons that have this status.

The task of finding such reasons is made more difficult by morality’s claim to unconditional authority, and to priority over all other values. A justification for such authority seems to require starting points that are peculiarly inescapable, and it may seem that reasons grounded in what is merely one value among others could not meet this test. Accordingly, many have attempted to justify morality by showing that it is entailed, or presupposed, by something to which everyone is committed. So, for example, Kant (1785) argued that we must take ourselves to be bound by morality in so far as we regard ourselves as rational agents, and Habermas (1990) has maintained that moral requirements are entailed by the idea of communication with others (see Habermas, J. §3; Kant, I. §9).

4 Justification as an aim of morality

Moral and political theories that may be broadly classed as ‘contractualist’ emphasize justification as an aim of morality (see Contractarianism §9). They argue, for example, that our thinking about right and wrong is guided by the idea of what could be justified to others on grounds they could not reasonably reject (Scanlon 1982), or that principles of justice are to be defended on the ground of their suitability to serve as public standards for the assessment of claims against the basic institutions of a society (Rawls 1993).

These ideas are related to questions of justification of the two kinds already discussed. First, it can be claimed that the aim of justifiability to others determines the content of justification within morality. Rawls, for example, concludes from the thesis just mentioned about the aim of justice that principles of justice and the basic institutions of a society must be justifiable on a basis that is independent of controversial world views and conceptions of the good life. Second, it can be argued that the value of being able to justify one’s actions to others has the right combination of connection with morality and independence of it to serve as an explanation of the significance that morality has for us. These claims are, however, controversial. Against them it can be maintained that the idea of justifiability to others lacks sufficient importance to account for the authority of morality and that some deeper standard of right and wrong must be presupposed as a standard of justifiability.

Moral knowledge

One possesses moral knowledge when, but only when, one's moral opinions are true and held justifiably. Whether anyone actually has moral knowledge is open to serious doubt, both because moral opinions are so hard to justify and because there is reason to think moral opinions are expressions not of belief (which might be evaluated as true or false) but of taste or preference. A successful defence of the view that people do have moral knowledge requires assuaging these doubts. Attempts in this direction standardly emphasize the respects in which our moral opinions, and the evidence we have for them, are analogous to the opinions and evidence we have concerning nonmoral matters, such as logic, mathematics, science, psychology and history. In the process they attempt to show that we do have good reason to think some of our moral opinions are true.

1 Confidence and evidence

People frequently, and quite casually, assume they have moral knowledge, in so far as they stand ready to act on the moral views they embrace. Yet people are circumspect when it comes to claiming moral knowledge, largely because so much of morality is controversial, but also because it is disturbingly difficult to defend in detail any particular moral view. Indeed, the confidence people have in their own moral convictions, although not easily shaken, often looks poorly backed by anything reasonably thought of as evidence or argument.

This apparent mismatch between confidence and evidence is largely explainable by noting that morality requires knowing how - how to act, react and feel - and not knowing that - that injustice is wrong, courage is laudable, kindness a virtue. One might well have the requisite abilities and skills without being able to articulate, let alone offer evidence for, one's moral views. Appreciating the practical dimension of morality is crucial to understanding its intimate connection with action. At the same time, it suggests that a proper account of morality must avoid an excessively intellectualized picture of the capacities it requires.

Still, on most accounts, people count as having moral knowledge, as opposed to moral virtue, only if (a) their moral beliefs are true and (b) those beliefs are justified. Thought of in this way, moral knowledge is an intellectual accomplishment. Against this background, arguments for thinking no one has moral knowledge commonly take one of two forms. Some hold that moral convictions are not properly seen as beliefs at all, which would mean we cannot satisfy (a). Others grant that people do have moral beliefs, but hold that such beliefs are all unjustified, which would mean we do not satisfy (b). A defence of moral knowledge must meet both threats (see Moral scepticism §3).

2 Noncognitivism

The first threat, posed by noncognitivists, usually travels with a positive account of moral convictions, according to which moral judgments reflect the preferences, or desires, of those who make them, but do not express beliefs. Noncognitivism finds support from the fact that moral opinions seem not to be empirically verifiable. As Hume put the point (1739/40), there appears to be no way to derive an 'ought' from an 'is', no way to establish a moral conclusion by appeal only to empirical premises (see Hume, D. §4; Logic of ethical discourse). G.E. Moore (1903) pressed this observation against all attempts to define moral claims in empirical terms, using what has come to be called the 'open question' argument (see Moore, G.E. §1). He maintained that all definitions of a moral term (say, 'good') using nonmoral terms (say, 'pleasure') are undermined by the fact that it always makes sense, in a way that it would not if the terms had the same meaning, to ask whether something describable by the empirical terms was describable using the moral term. It makes sense, for instance, to ask whether something pleasant is good in a way that it does not make sense to ask whether something pleasant is pleasant. Moore himself concluded that moral claims describe non-empirical, *sui generis* facts (see Intuitionism in ethics). Noncognitivists, in contrast, have held that if a claim is not empirically verifiable, it does not describe anything whatsoever. They conclude that the open question argument shows that moral claims, precisely because they cannot be defined in empirical terms, have no (descriptive) meaning and so cannot express beliefs (see Analytic ethics).

Noncognitivists frequently come to the same conclusion via another route by appealing to the apparently intimate connection between thinking that some action is morally required or good and being motivated (at least to some degree) to perform it. This connection is easily explained, the noncognitivists note, once we see moral 'beliefs'

not as genuine beliefs but instead as motivational states akin to desires or preferences (see Moral motivation §§1-2).

Whichever way one comes to the conclusion that moral claims do not express beliefs, the implications for moral knowledge are the same. For if a person's moral view fails to express a belief then that view, however salutary, cannot rightly be dignified as knowledge.

Against this threat, many cognitivists argue that, on a suitably sophisticated understanding of empirical verification, moral claims actually are verifiable. And they maintain that the open question argument establishes at most that moral claims are not synonymous with empirical claims, not that they are empirically unverifiable. Others, though, grant that moral claims are not empirically verifiable, but argue against empirical verifiability as a proper criterion for meaningfulness. As for the connection between moral conviction and motivation, cognitivists either deny that the connection is as intimate as the noncognitivists suppose, or argue that the intimate connection can be just as well explained without abandoning the view that moral convictions are expressions of belief. However these particular responses play out, cognitivists regularly stress the extent to which moral convictions resemble beliefs. We see them as answerable to evidence and argument, talk of them as true or false, and distinguish between those who know right from wrong and those who do not. All of this suggests that adopting a moral conviction is a matter of forming a belief about how things are morally.

3 Scepticism

The second threat to moral knowledge, posed by sceptics, leaves unchallenged the contention that we have moral beliefs. Instead, it attacks our right to see these beliefs as justified. We may believe that deliberate cruelty is wrong, and that slavery is unjust, but (the sceptic maintains) we have, at bottom, no good reason for thinking such beliefs are true.

The sceptical challenge, to the extent it raises a special problem for *moral* knowledge, depends on drawing a contrast between moral and nonmoral beliefs that shows the former to be especially suspect. Three considerations are standardly marshalled in support of such an unflattering contrast.

The first is that even a cursory glance across cultures, or back through history, reveals an astonishing diversity of moral views (see Moral relativism). That people so frequently come to such different, and incompatible, opinions makes the thought that they form their opinions in response to evidence or argument radically implausible. At the same time, the diversity exhibits a telling pattern. It looks as if the opinions people hold by and large reflect either their own interests or the interests of the powerful. This recommends seeing the moral views people embrace as mere rationalizations or as reflections of systems of social control and regulation (see Ideology). Either way, moral beliefs emerge as views we have no reason to think true - even when the views happen to be advantageous.

The second consideration picks up on Hume's point that there is an unbridgeable gap between 'is' and 'ought' and highlights the way in which, in defending one moral belief against others, we seem inevitably to appeal to other moral commitments that are equally contentious. In arguing with particular people we sometimes find common ground and can proceed, using our shared assumptions, to resolve a debate. The resolution is available, however, only because we share some moral view with them that others could reasonably challenge. To meet such a challenge, rather than ignore it or oppose it with force, we will (again inevitably) need to appeal to some other moral view in order to defend the one in question. Yet we will then just be pushing the issue back, finding ourselves appealing to another assumption which is itself either unsupported or supported by an undefended moral assumption. Thus the is/ought gap appears to entail that the only defence one might offer of one's moral beliefs is one that illegitimately presupposes others. So again our moral beliefs emerge as views we have no reason to think true - even when we can appeal to some in defending others.

The third consideration focuses on what the world would have to be like in order for our moral beliefs to be true and justified. Moral facts putatively stand as authoritative guides to action. Yet it is hard to make sense of this authority at all, and harder still to reconcile such authority with a plausible view of the natural world. Moreover, if there are moral facts, they are presumably connected in some way to various nonmoral facts. After all, we often appeal to nonmoral facts to explain moral ones, saying for instance that some action is good because it causes pleasure. But the connection between these nonmoral facts and the moral facts looks to be utterly mysterious. Perhaps most troubling of all, there seems to be no good way to explain how we discover these peculiar facts and

their connection to the more mundane facts upon which they supposedly depend. These difficulties all provide reason to think the world is not the way it would have to be in order for our beliefs to be true and justified (see Moral realism §6; Naturalism in ethics). This time our moral beliefs emerge not only as views we have no reason to think true, but as views we have positive grounds for rejecting as false.

Against the sceptics, those who hold that moral beliefs are sometimes justified standardly note, to start, that moral disagreement is not as widespread as the sceptics suggest nor noticeably more common than disagreements concerning empirical matters. At least when it comes to fundamental moral principles (concerning, say, the value of life, the importance of honesty, the nobility of courage) there is actually a striking consensus. Disagreements at a less fundamental level are, of course, common. Yet these disagreements frequently turn on differences of opinion concerning plain matters of fact. When they do not, the arguments we offer on behalf of a particular moral view will, as the sceptic says, inevitably implicate further moral assumptions. However, in this respect, moral arguments resemble nonmoral arguments in that the latter too must always be advanced against a background provided by additional (in these cases, nonmoral) assumptions. Indeed, whether the disagreements are moral or not, almost any argument one side offers will appeal to considerations the other side might intelligibly call into question. Thus, it seems, neither of the first two considerations advanced by sceptics stands as an especially strong argument for thinking our moral beliefs suffer by contrast with other sorts of beliefs we readily acknowledge as (sometimes) justified.

In response to the third consideration, many argue that neither moral facts nor our epistemic access to them are as mysterious as sceptics maintain. To a large extent, the suggestion that moral facts, and so our access to them, would have to be mysterious rests on rejecting the view that such facts are reducible to, or constituted by, natural facts. Yet the standard arguments against naturalism, which appeal to the open question argument and the is/ought gap, lose much of their force in light of recent developments in semantics and metaphysics. Such developments suggest, first, that the open question argument mistakenly assumes that moral and nonmoral terms can refer to the same property only if they are synonymous and, second, that our inability to infer moral conclusions from nonmoral premises is no more significant than our similar inability to infer biological or psychological conclusions from nonbiological or nonpsychological premises. If naturalism concerning moral facts is defensible, then our epistemic access to moral facts is no more puzzling than is our access to nonmoral facts, even if it is sometimes more tenuous.

Whether or not naturalism is, in the end, defensible, many argue that we have strong evidence for some of our moral views anyway. They make their case by emphasizing the significant respects in which the evidence we have for our moral views is analogous to the evidence we can marshal for certain nonmoral views. Moral sense theorists, for instance, see some moral beliefs as analogous to perceptual judgments and suggest these justify our other moral views in much the way perception provides support for our scientific theories (see Moral sense theories). Alternatively, intuitionists and rationalists maintain that we come to know certain moral truths - truths that can then provide evidence for others - in just the way we come to know certain fundamental truths of mathematics or logic, by relying on reason and reflection. These particular proposals usually play out against the assumption that justification is possible at all only if at least some fundamental beliefs can serve to justify others without themselves needing support. But even those who reject this foundationalist view, and embrace instead a coherentist conception of justification, argue that moral beliefs, no less than various nonmoral beliefs, are justified to the extent that they stand in relations of mutual support (see Knowledge and justification, coherence theory of; Foundationalism). The common thread in all these suggestions is the persistent pressure to recognize that our grounds for accepting particular moral views are not significantly different in kind from the grounds we have for other views that are standardly thought to be unproblematic. And the suggestion is that experience, reason and reflection, which are the main tools we have for learning about the world, may help us as well in coming to a justified view of morality.

Moral luck

The term 'moral luck' was introduced by Bernard Williams in 1976 to convey the idea that moral status is, to a large extent, a matter of luck. For example, that Bob grows up to be vicious and Tom to be virtuous depends very much on their different family conditions and educational background. Following Williams, Thomas Nagel widened the scope of moral luck. The position taken by both stands in stark contrast to the widely-held view, influenced by Kant, that one is morally accountable only for what is under one's control, so that moral accountability is not a matter of luck. This idea is so deeply entrenched in our modern concept of morality that rejecting it would call for a rethinking and reformulation of the most basic notions of morality. Some have argued that the paradox of moral luck provides a strong reason to abandon traditional moral theories, and lends support to virtue ethics.

1 Domains of moral luck

Bernard Williams introduced the term 'moral luck' in 1976, to convey the idea that moral status is largely a matter of luck. Williams' main interest lies in how luck may influence agents' reflective assessment of their actions, that is, in their ability to justify rationally their decisions and actions to themselves. He uses the example of Gauguin, who abandoned his family to pursue his artistic aspirations in Tahiti. In Williams' view, whether Gauguin's choice can be justified depends on the success of his venture, a success not entirely under his control and, thus, in part, a matter of luck. Two obstacles block the agent's capacity to guarantee retroactive justification in such decisions. First, at the time of the decision-making the agent can never know how things will turn out. Second, in projects like that of Gauguin's, the project often changes the very character and attitudes of the agent. The Gauguin at the time of the decision has no way of knowing whether Gauguin after the decision will approve retroactively of the project (see Williams, B.A.O. §2)

While Williams is concerned mainly with luck from the 'subjective' point of view, namely, with how agents relate to the justification of their own actions, Thomas Nagel seeks to show the influence of luck from a more 'objective' point of view. According to Nagel (1976), luck affects morality in four ways. The first is 'constitutive luck', luck in the kind of person one is, which depends, at least partially, on factors beyond one's control (such as heredity and environment). The second is 'circumstantial luck', luck in the kind of problems and situations one faces. Nagel offers the example of some young Germans who were morally lucky to have left Germany in the early 1930s. Had they stayed, they would have been faced with a terrible moral test which many of them would probably have failed. Thus, according to Nagel, whether or not a person became a Nazi murderer was, to a significant extent, a matter of circumstantial luck.

The other two ways luck is believed to influence morality have to do with the causes and effects of actions. One is concerned with the way antecedent circumstances determine the acts of the will itself (see Will, the). If determinism is true, then our very choices are beyond our control, and thus a matter of (good or bad) luck (see Free will). The other and last kind of luck, sometimes referred to as 'resultant luck', is luck in the outcome of one's actions and projects. This includes cases of decisions made with uncertainty, as when a political leader decides to go to war knowing full well at the time of the decision that if the venture fails, the decision can never be justified retroactively; and cases of negligence, such as that of two reckless drivers, one of whom is lucky, not causing any injury, the other being unlucky, hitting a child crossing the road. The independence of these different kinds of luck from one another makes life difficult for critics of moral luck. To sustain the alleged immunity of morality to luck, they have to show that each and all of them have no effect of morality.

Attempts to apply the contemporary debate on moral luck to ancient philosophy focus on another aspect of luck, namely, its relation to wellbeing. Some ancient schools, especially those of the Cynics and Stoics, argued that immunity to luck is a necessary condition for wellbeing, while others, notably Aristotle, emphasized the essential vulnerability of human happiness (eudaimonia) (see Cynics; Stoicism; Aristotle §21; Eudaimonia). According to Martha Nussbaum (1986), their different attitudes towards the role of luck mark an important difference between Aristotle and Plato (see Plato).

2 Arguments for and against moral luck

To resolve the paradox of moral luck, some have criticized the vivid examples presented by Williams and Nagel. With regard to the lucky and unlucky drivers, for example, it has been argued that our different ways of relating to them are not to be explained by reference to the drivers' ultimately different moral status - they were equally reckless - but to our epistemic shortcomings. In most cases, we know about other people's personalities and intentions only through their actual behaviour. Hence, contra Williams and Nagel, luck does not affect one's real desert, but only our knowledge of it.

Proponents of moral luck have argued that any attempt to detach ourselves from the unintentional and unforeseen aspects of our actions would make it impossible for us to retain our identity and character as agents. Since every aspect of our moral life results from factors which are beyond our control, there seems to be nothing left for us to be responsible for and the area of genuine agency, the traditional locus of moral judgments, shrinks to an extensionless point. Such a detachment also carries with it unwanted normative implications. If responsibility were to be limited strictly to what is under our control, we would be able to walk away from the sick, the old, and the otherwise helpless, provided their helplessness was not an intended result of any agent's actions. A world without moral luck, that is, a world where the boundaries of our responsibilities are determined by what is under our control, would thus be - on this argument - a place in which most of us would not want to live (see Responsibility §§2-3; Desert and merit §§2-3).

3 Theoretical implications

Acceptance of the existence of moral luck has significant implications for ethical theory. Williams and others have argued that the paradox of moral luck provides us with a powerful reason to abandon the ethics of duty and to adopt some kind of virtue ethics (see Virtue ethics). Virtue ethics is expected to escape the problem of moral luck by focusing on good and bad traits of character, instead of on notions of moral responsibility and blame. While we refrain from attributing responsibility and blame in cases where luck is involved in the action under question, we do not change our judgment of character if having a certain character is a matter of luck.

Allowing luck to encroach into the realm of morality means assigning less importance to the category of the voluntary, as the boundaries of our responsibility and obligations would on this view extend beyond the limits of our voluntary actions. If moral luck exists, we might be accountable for results we could not control, and we might be responsible for other people even if we never voluntarily committed ourselves to them. Since reference to the voluntary versus the nonvoluntary seems to be embodied in the very notion of the 'moral', acceptance of moral luck would imply abandoning, or assigning much less significance to, the common distinction between the moral and the nonmoral. Such a move is indeed made by most proponents of moral luck.

Moral motivation

Questions about the possibility and nature of moral motivation occupy a central place in the history of ethics. Philosophers disagree, however, about the role that motivational investigations should play within the larger subject of ethical theory. These disagreements surface in the dispute about whether moral thought is necessarily motivating - 'internalists' affirming that it is, 'externalists' denying this.

The disagreement between externalists and internalists reflects a basic difference in how the subject matter of ethics is conceived: externalism goes with the view that ethics is primarily about the truth of theories, construed as sets of propositions, while internalists see morality as a set of principles meant to guide the practical deliberations of individual agents. Internalists interpret questions of objectivity in ethics as questions of practical reason, about the authority of moral principles to regulate our activities. Here controversy has centred on whether the authority of practical principles for a given agent must be grounded in that agent's antecedent desires, or whether, instead, practical reason can give rise to new motivations.

There are also important questions about the content of moral motivations. A moral theory should help us to make sense of the fact that people are often moved to do the right thing, by identifying a basic motive to moral behaviour that is both widespread and intelligible, as a serious source of reasons. Philosophers have accounted for moral motivation in terms of self-interest, sympathy, and a higher-order concern to act in accordance with moral principles. But each of these approaches faces difficult challenges. Can egoistic accounts capture the distinctive character of moral motivation? Can impartial sympathy be integrated within a realistic system of human ends? Can we make sense of responsiveness to moral principle, as a natural human incentive?

1 Internalism and externalism

Internalism states that moral considerations are necessarily motivating for those who grasp them. The most common version of this position is the claim that sincere acceptance of a moral judgment implies that the person who accepts it has some motive - not necessarily overriding - for compliance with the judgment. Externalists deny this, insisting that one might sincerely accept a moral judgment without any corresponding motivation. On this view, psychological questions about human motivation are completely distinct from issues about the truth of moral judgments or the nature and constitution of moral facts (see Moral judgment §1; Moral realism §1).

The categories 'internalism' and 'externalism' were introduced only in the middle of the twentieth century. It is often unclear how exactly these categories are to be understood, inviting confusion about their precise extension. (Which moral judgments are supposed to be motivationally effective? How are we to understand the notion of a motive that is present, but not necessarily overriding?) So it is often hard to classify moral philosophers as internalists or externalists as such.

Nevertheless, David Hume is presumably giving voice to an internalist point of view when he makes central to his theory the idea that 'morals excite passions, and produce or prevent actions' (1739/40: 457). In characteristic internalist fashion, Hume interprets this idea as placing the important constraint on an account of moral distinctions that it must explain how grasping moral distinctions could immediately give rise to passions and actions, in the way it seems to do. By contrast, the hermetic distinction drawn by John Stuart Mill (1861), between the proof of the principle of utility and the sanctions for compliance with it, suggests an externalist position. On this position, it would be possible to accept a moral principle without having any tendency to act in accordance with it; the question of the truth of a moral principle is thus taken to be completely distinct from the psychological issue of whether and how the principle can be rendered effective in people's motivations (see Hume, D. §4; Mill, J.S. §§7-8).

2 Implications

The issue of moral motivation is a crux in discussions about the nature and status of moral judgments and moral values. Noncognitivists, who hold that moral judgments express emotions or preferences rather than report genuine truths, often start out by affirming that moral judgment is directly motivating, a version of internalism (see Moral Judgment §1; Emotivism). Underlying the position that only noncognitivism can explain this fact is the assumption that the cognitive states through which we grasp judgments capable of genuine truth are motivationally inert.

In a more metaphysical vein, irrealists or error theorists, who deny the reality of moral values in the world, similarly argue from internalist assumptions. Real moral values would have to have the distinctive property of affecting the will directly. But, it is argued, items with this property would be mysterious-utterly unlike the other kinds of things with which we are familiar in the world-and so we should be reluctant to include them in the inventory of reality (see Moral realism §7).

Philosophers who wish to resist these conclusions may either accept internalism, and try to show that cognitivist or realist views can account for the motivational effects of ethical reflection, or reject internalism (see Moral realism §§4-5). Those who pursue the second option need not deny that people are often motivated to do what they judge to be morally right or good. Like Mill, however, they insist that motivations of this kind are not necessarily built into moral reflection; rather it is the task of moral education to supply them.

The interest of this dispute lies in its connection with fundamentally divergent ways of thinking about moral objectivity and the subject matter of ethics. Externalism goes naturally with the view that moral philosophy is essentially about moral theories, construed as sets of propositions setting out what it is morally right or good to do. On this conception, questions of objectivity in ethics turn primarily on the truth of the propositions that make up competing moral theories. But whether a given proposition is true or false seems independent of the psychological question of whether and how people may be moved to act in accordance with it. Taking this approach seriously, we may be led to the conclusion that the true moral theory should be esoteric, so that the theory itself provides good reasons for discouraging people from accepting it, a conclusion countenanced by Sidgwick and other utilitarians (see Sidgwick, H. §2).

Internalist approaches, by contrast, conceive of moral philosophy as dealing with common principles for public moral discourse and practical deliberation. On this view, the issue of objectivity in ethics is conceived primarily as an issue of practical reason, about the title of moral principles to regulate our activities. Moral reflection is accordingly thought of as a form of practical deliberation, yielding verdicts about what is to be done, and questions about the truth of moral propositions assume a subsidiary role. If we conceive of the subject in this way, then some form of internalism will seem inevitable, since it is the distinguishing mark of practical deliberation that it affects the will directly. Furthermore, it will hardly make sense to suppose that the criteria of right defined by the correct moral theory should be esoteric, since the kind of objectivity aimed at primarily in ethical theory is precisely an objectivity within practical reason (see Practical reason and ethics).

3 Reason and desire

Within the internalist camp, there are striking disagreements about the degree to which the motivational consequences of practical reason effectively constrain our philosophical options. On one side are the Humeans, who hold that practical reasoning must always be grounded in the noncognitive psychological states of individual agents - what Bernard Williams calls their ‘subjective motivational sets’ (1980) (see Williams, B.A.O. §3). Combined with internalism, this view has the consequence that moral principles are hostage to antecedent, empirical facts about the motivational sets of the agents to whom the principles apply. This conclusion in turn exerts some pressure in the direction of relativism, since motives to comply with moral principles may, as a matter of empirical fact, fail to show up in the subjective sets of all agents (see Moral relativism).

On the other side, Kantians deny that empirical facts about people’s subjective motivational sets place substantive restrictions on the content or normative force of moral principles. They point out that any theory of practical reason must allow for the phenomenon of motivational irrationality (see Akrasia). Thus I may fail to take steps that I know to be necessary if I am to attain some end that I hold dear. The principle that I ought to pursue those means that are necessary for realizing my ends does not entail that I will necessarily be motivated accordingly, but only that I will be motivated accordingly in so far as I am rational. This has been pointed out by Christine Korsgaard (1986). If she is right, then it cannot be inferred from the fact that a given agent lacks an empirical motive for compliance with a candidate principle that the principle is not binding on the agent, since it is possible that the agent is irrational. To decide whether that is the case, however, we will need to determine - in a way that is not circumscribed by antecedent facts about people’s motives - the content of principles of practical reason.

A central question in this dispute concerns the role of desires in the explanation of motivation. Humean resistance to the idea of practical principles that are not grounded in people’s subjective sets stems from the idea that

motivation is essentially a noncognitive orientation to the world. Kantians - most notably including Thomas Nagel (1970) - have granted that motivation always involves a state of desire, but suggested that reasoning in accordance with practical principles may give rise to new desires, so that the validity of such principles for a given agent need not be constrained by the items already contained in that agent's subjective motivational set (see Nagel, T. §5).

4 Explanation and justification

However this dispute is resolved, it cannot be denied that the disposition to respond to moral principles is reliably awakened and strengthened in the normal course of human psychological development. Furthermore, moral reasons often weigh heavily with people in their practical deliberations, leading them to take remarkable steps to avoid doing what would be wrong. It seems a reasonable constraint on moral theories that they should help us to make sense of these facts. A theory on which it appeared utterly mysterious that people naturally respond to moral considerations and take them seriously in their deliberations would be to that extent implausible.

What is needed is an account of the content of our moral incentives. Moral theories typically identify some common pattern of motivation, such as sympathy or self-interest, and try to show how motivations of that type might lead people to comply with principles of right, as the theory characterizes them. In practice, human motives are heterogeneous, complex and fluid; why should we suppose that there is any general account to be had of our responsiveness to moral considerations? This supposition is linked to two controversial normative assumptions. First, there is the assumption that moral considerations hang together in such a way that a uniform account can be provided of what makes actions morally wrong (in terms, for instance, of the effects of the actions on general utility, or the failure of universalizability). Philosophers who accept this assumption naturally expect to find a complementary general pattern of moral motivation, while those who deny it - some virtue theorists, perhaps - will be more sceptical.

Second, it is commonly assumed that modern morality aspires to a kind of objectivity within practical reason, providing public principles that make claims on virtually all agents. Here controversy centres not so much on whether morality represents itself as authoritative in this way, as on its title to such authority. How this controversy is resolved will depend in part on whether we can identify incentives to moral behaviour that are both widespread in human nature and intelligible as serious sources of reasons, for the availability of such common motivational structures would seem a necessary condition for the objective authority of morality.

It would not, however, be sufficient. If Nietzsche and Freud are right, for instance, then there are common motivational structures at the root of moral responsiveness, involving internal mechanisms for enforcing compliance with moral norms that draw on the redirection of aggressive impulses back against the self (see Nietzsche, F. §§8-9; Freud, S. §8). These accounts suggest a ready explanation of the urgency with which moral demands are invested in the deliberations of many agents; indeed, they have the further advantage of being able to explain the characteristic pathologies of the moral life, such as moralistic forms of extreme self-denial. But the explanations provided by these accounts seem to undermine rather than to vindicate the authority of morality, suggesting that the common patterns of moral motivation are essentially harmful for the individuals subject to them.

This shows that the authority of morality will depend not just on the availability of a common incentive to moral behaviour, but on the content of the common incentive that is identified. An account of moral motivation congenial to morality's normative ambitions would, at a minimum, identify a motive to moral behaviour that can be cultivated without necessarily causing dire psychological harm to the individual who has the motive. Beyond this, an effective moral motive should be capable of being integrated within an agent's overall system of ends, so as to produce a stable and self-reinforcing personality.

5 Egoism and self-interest

Very few philosophers accept egoism, construed as the psychological thesis that our motives are uniformly self-interested. This bald thesis flies in the face of the many occasions on which people act without any apparent concern for their own interests, however broadly conceived. Even when our motives are self-interested, the specification of our interests would seem to presuppose some core of nonegoistic concerns, a point well made by Joseph Butler (1726) (see Butler, J. §3; Egoism and altruism §3).

Still, self-interest is an undeniably widespread and powerful pattern of motivation, and this makes it an obvious candidate in terms of which to reconstruct moral concern. Thus, suppose that compliance with moral principles could be shown to conduce to the long-term interest of each individual. We would then have a ready explanation to hand of the ease with which moral incentives emerge in the course of psychological development, and of the urgency with which moral considerations present themselves in practical deliberation: these phenomena would reflect the natural concern of humans for their own wellbeing, and the equally natural use of practical reason in the service of this concern. This explanation would in turn support rather than undermine the authority of morality. Those who make morality regulative of their activities would thereby achieve integration and stability of personality in an exemplary degree, since morality, far from being inimical to our other interests, would represent the condition for their effective pursuit.

This broadly Hobbesian strategy for understanding morality rests on the idea that each of us benefits enormously from the availability of certain public goods - such as peace, security, and trustworthiness - that can be secured only through general compliance with moral norms (see Prudence §2; Hobbes, T. §5). Discussions of the strategy have become highly sophisticated, drawing on advances in the theory of rational choice (see Rational choice theory). But the increasing sophistication of its formulation cannot compensate for the inadequacy of the strategy as an account of moral motivation. The strategy might show that something like moral norms make claims on all of us. But to the extent that our incentive to comply with these norms is self-interest, the norms themselves seem to lose their distinctively moral character, for it is part of our understanding of moral requirements that they are to be followed even when it is inexpedient for us to do so. The problem is made vivid by the figure of the prospective ‘free rider’, who asks why they should comply with social norms when sufficiently many other people follow them to secure the public goods of cooperation. However this question may be answered, the very fact that it needs to be asked shows that the prospective free rider is not an ordinary moral agent at all.

6 Altruism and sympathy

A genuinely moral agent - as opposed to an egoist - is altruistic, in the sense of having some immediate concern for the interests of others. Furthermore, the capacity for sympathetic identification seems natural to human beings; it is the rare person who is not directly moved by exposure to human suffering, and this tendency to sympathetic response can be nurtured through moral education. For these reasons, many have followed Hume and Schopenhauer (1840) in taking sympathy to be the paradigmatic moral motivation (see Hume, D. §4; Schopenhauer, A. §6; Moral sentiments §1).

If sympathy is to play this role, however, then it will need to be corrected and refined. Actual sympathy is notoriously partial and erratic, directed (for instance) at those individuals with whom one has some personal connection, whereas morality seems to demand impartiality of response. Thus, whether morality requires that I help a given person should not depend just on whether I happen to know them, but also (for instance) on the comparative urgency of the claims of others. The standard way to deal with this problem is to subject the mechanism of sympathetic identification to the discipline of impartial reflection. One is to adopt the perspective of an informed spectator, abstracting from one’s knowledge of one’s own position in the world, and treating each person’s welfare as equally important; the morally right action is what sympathy, refined by this procedure of reflection, would then lead one to approve of. Though liable to many different interpretations, this general approach to moral motivation has been associated traditionally with utilitarianism (see Impartiality §§1-2; Utilitarianism).

The utilitarian approach yields an impersonal conception of ethical impartiality, on which moral requirements take an agent-neutral rather than agent-relative form. Consider the familiar moral prohibition on murder. This is ordinarily understood as an agent-relative requirement, proscribing my killing another person even if by doing so I could prevent a number of other murders. But a prohibition of this kind would not survive utilitarian impartial reflection. Once we abstract from our knowledge of our local position in the world, it is no longer possible to sustain a proprietary concern for the character of our own actions. When sympathy is subjected to a filter of impersonal reflection, it can only endorse requirements that are agent-neutral in form, and hence capable of being accepted and acted on by any other agent as well (an injunction to prevent murder, say, instead of the conventional agent-relative prohibition on killing people oneself). In this way, the impersonal interpretation of impartiality defines a standpoint that is available to be occupied by any moral agent.

Questions arise, however, about the authority and motivational effectiveness of the claims made from this point of view. To take the latter first, it is supposed to be an advantage of the utilitarian approach that it accounts for moral motivation in terms of the familiar operations of sympathy. But there is a vast difference between the immediate, impulsive sympathy that develops naturally in human beings and the impersonal concern to maximize the good. The utilitarian claims that sympathy is transformed into a responsiveness to agent-neutral reasons as a result of moral reflection, but one may wonder whether sympathy, thus transformed, remains a natural pattern of motivation.

As for authority, the question is whether impersonal sympathy can be integrated into a person's system of ends. It gives us a standing first-order aim - the maximization of the good - which is set over against our other first-order aims, and likely to conflict fundamentally with them (given the demands that the maximization of the good notoriously imposes on individuals). The result is that we must either radically curtail the pursuit of our ordinary interests for the sake of morality, or resign ourselves to living in a way that is not morally justifiable. Utilitarians reply that morality is a hard thing, and that we should not expect to be able to accommodate its demands within the contours of ordinary bourgeois life. But the difficulty of integrating impersonal sympathy within a normal system of human ends is likely to raise a doubt about the authority of a morality construed in these terms: by what right does it demand this degree of sacrifice of us?

7 Principle-dependent motives

Kantian approaches typically trace moral concern to a higher-order motive, such as the concern to act only in ways that are permitted by moral principles (see Kantian ethics). Motives of this type will sometimes give an agent first-order ends, namely when moral principles require a certain course of action (keeping a promise, say). But when moral principles do not impose requirements in this way it will be open to agents to pursue their first-order ends while at the same time completely satisfying their higher-order moral concern. Morality regulates our first-order pursuits, but because the moral motive does not automatically supply a standing first-order end it is not inevitably in conflict with those pursuits, and so the possibility of integrating moral concern within a realistic system of human ends is left open.

Whether this possibility is realized will depend on the content of moral principles. If those principles instructed us always to maximize the good, then they would in effect determine a standing first-order end. In that case the higher-order concern to act in ways that are permitted by moral principles might be as difficult to integrate with our other ends as impersonal sympathy would be. But Kantians reject such maximizing interpretations of morality, taking moral requirements to derive from reflection on the universalizability of our aims, and contending that these universality procedures yield specific agent-relative obligations that function as limiting conditions on our activities (see Universalism, ethical §5).

The idea that morality supplies a higher-order motive invites the charge that it is self-indulgent, reflecting a fastidious concern for one's own virtue rather than a direct responsiveness to the needs of others. Further, the involvement of moral principles in Kantian moral motivation seems to deny moral worth to spontaneous and heartfelt actions, and threatens to erect an alienating screen of reflection between moral agents and their projects. A more fundamental question is whether the motive of duty can be rendered intelligible, as a natural human incentive. Why should the concern to act in ways that are universalizable emerge so readily in moral development, and present itself to us as a serious source of reasons?

To this, Kant (1785) replies that the motive of duty is constitutively rational, and that acting on it enables us to realize the supreme good of autonomy (see Kant, I. §9). Somewhat less ambitiously, T.M. Scanlon (1982) observes that people commonly want to be able to justify their conduct to others on grounds that could not reasonably be rejected, arguing that moral principles tell us what we have to do to satisfy this familiar desire. Either of these strategies might derive support from the readiness with which people respond to 'golden rule' arguments, in which we invite them to consider what it would be like to change positions with those who would be affected by their actions (see Universalism, ethical §4). This phenomenon suggests that the concern to act in ways that are universalizable may be a powerful and *sui generis* pattern of human motivation.

Moral particularism

Moral particularism is a broad set of views which play down the role of general moral principles in moral philosophy and practice. Particularists stress the role of examples in moral education and of moral sensitivity or judgment in moral decision-making, as well as criticizing moral theories which advocate or rest upon general principles. It has not yet been demonstrated that particularism constitutes an importantly controversial position in moral philosophy.

Moral particularism is the view that general moral principles play less of a role in moral thought than has often been claimed. In its most extreme form, particularism states that there are no genuine moral principles, and that therefore moral agents who attempt to guide their action by reference to moral principles, and philosophers who attempt to construct moral theories based on principles, are seriously mistaken (see Moral realism §5; Situation ethics).

Many particularists are influenced by the view of Wittgenstein that one acquires a concept not by being taught some universal rule for its application, but through introduction into a human practice and a way of seeing things (see Wittgensteinian ethics §3). The particularist view of moral education will stress the importance of examples and actual experience of individual moral cases rather than the learning of universal moral rules under which particular cases can be subsumed (see Examples in ethics §2; Moral education §3).

A link is often drawn between moral particularism and so-called 'antitheory' in ethics. Antitheorists suggest that ethical theorists are in error in postulating principles according to which actions are right to the extent that they are in accord with these principles. Utilitarianism, for example, claims that acts are right to the extent that they maximize utility (see Utilitarianism). A further link is often alleged between particularism, anti-theory and virtue ethics (see Virtue ethics). But this link may rest on a confusion between particularism about moral theory and particularism about moral agency. Virtue ethics has its own principle: right actions are those that the virtuous person would do. The virtuous person will indeed not in practice proceed by attempting to apply this principle directly. Here, however, virtue ethics and utilitarianism are in agreement, since most utilitarians have claimed that moral agents should not attempt to apply utilitarianism in practice.

Moral particularism can also emerge out of the theory of reasons for action. On the view of Dancy (1993), reasons are not universalizable across cases, so that what counts as a reason in one case need not be assumed to function as a reason in the same way in other cases (see Logic of ethical discourse §7). My enjoying giving you a present counts in favour of my action; but my enjoying torturing you counts against. Against this, it can be suggested that reasons are universalizable at a higher level (*innocent* pleasure, perhaps, always counts as a reason), and that to deny this is to embrace a form of irrationalism.

According to less extreme particularists, principles can play some role in theory and in practice (see Casuistry). On one view, they serve as useful generalizations, but there is always a need for judgment in particular cases (see Moral judgment §2; Theory and practice §2). Aristotle is best seen as such a particularist. Once again, it is not clear that, for example, utilitarians or Kantians would wish to deny such a role for judgment (see Kantian ethics; Universalism in ethics §3).

Moral pluralism

Moral pluralism is the view that moral values, norms, ideals, duties and virtues are irreducibly diverse: morality serves many purposes relating to a wide range of human interests, and it is therefore unlikely that a theory unified around a single moral consideration will account for all the resulting values. Unlike relativism, however, moral pluralism holds that there are rational constraints on what can count as a moral value. One possible, though not necessary, implication of moral pluralism is the existence of real moral dilemmas. Some philosophers have deemed these to be inconceivable; in fact, however, they do not constitute a serious threat to practical reason. Another possible implication of moral pluralism is the existence within a society of radically different but equally permissible moralities. This poses a challenge for political philosophy, and might justify a liberal view that particular conceptions of the good life ought not to be invoked in the formulation of public policy.

1 Moral pluralism and moral theory

Moral pluralism is the view that moral values, norms, ideals, duties and virtues cannot be reduced to any one foundational consideration, but that they are rather irreducibly diverse. As such, moral pluralism is a metaphysical thesis, in that it tells us what moral considerations there are. Pluralist moral philosophers disagree as to exactly what the plural sources of moral value are. For example, Sir David Ross (1930) distinguished six species of duty, including duties of fidelity and reparation, of gratitude, of justice, of beneficence, of self-improvement and of non-maleficence; and Thomas Nagel (1979) has claimed that the conflicts among diverse moral principles are due to there being five distinct sources of value - special allegiances, universal rights, utility, perfectionist ends of self-development, and individual projects (see Nagel, T. §5). Despite the differences between these accounts of the sources of moral value, the resolution of which constitutes a challenge for substantive moral theory, these thinkers can be seen as united in the view that morality has developed to protect and promote basic interests related to human wellbeing and flourishing, but that since there is no unique form that human wellbeing must take, there can consequently not be a theory of morality unified around one supreme value (see Happiness §3; Welfare).

This is not to say that the truth of moral pluralism disqualifies any attempt at formulating a moral theory (see Morality and ethics §§1-2). Among the many moral values which human beings pursue, there are undoubtedly some that can be grouped together and accounted for in terms of some more general value relevant to the particular set of human interests with which they are all in one way or another concerned. Moral pluralism implies simply that none of these values could plausibly claim hegemony over the entire set of moral considerations.

Historically, moral pluralism has been linked with controversial positions in moral epistemology and the ontology of value, according to which moral facts are real and non-natural, and are given as self-evident to a distinct human faculty of moral intuition (see Moral realism; Intuitionism in ethics). It is in fact compatible with a wide range of philosophical positions on these issues, including anti-realism and naturalism.

Some philosophers have argued that the diversity of our moral concepts is a distinctive feature of modernity. Alasdair MacIntyre, for example, has claimed that the plurality of conflicting considerations which make up the moral lexicon of the modern agent is a sign of cultural decay. Modern morality is for MacIntyre a congeries of concepts which have been inherited by modern agents from past forms of life, but which have been torn from the coherent concrete human practices within which they originated, and in the context of which alone they have any real meaning. Moral pluralism is therefore in his view a symptom of our moral discomfiture.

Moral pluralism has also been challenged by defenders of classical single-principle moral theories. Yet there have also been signs of theoretical rapprochements. Indeed, many modern consequentialists are abandoning the simple view of human wellbeing embodied in classical utilitarianism in favour of more multifaceted accounts (see Consequentialism). And many deontologists can be read as formulating rational priority rules ranking deontological constraints over other types of moral considerations, rather than as banishing the latter completely from the realm of the moral (see Deontological ethics).

2 Relativism and moral dilemmas

It is important to distinguish moral pluralism from a thesis with which it has too often been confused, namely that of moral relativism. A relativist claims that the truth of moral judgments is relative to the conventions of the social

group (or even to the individual whim) of the person issuing the judgment, and that these conventions or whims are not themselves subject to any further criterion of adequacy. There are therefore according to relativists no rational constraints on what can count as a moral value, and it is therefore senseless in their view to speak of the truth, falsity or justification of moral judgments (see Moral relativism). Moral pluralism in contrast holds that while the variety of moral principles applying to human beings is irreducible, it is not infinite. Rather, there are constraints on what can count as a moral value (and there is therefore sense in speaking of moral truth and falsity). These constraints might, for example, have to do with the (inherently diverse but not infinite) forms which human wellbeing and flourishing can take.

Moral pluralism is therefore compatible with the existence of rational constraints upon moral thought.But the fact that a number of statements to do with moral value might all be true while apparently recommending incompatible actions, and that real, as opposed to merely apparent, moral dilemmas emerge as a real possibility, has been thought by some philosophers to disqualify it as a theory of value by making it sin against basic axioms of deontic logic. These include the principle that ‘ought implies can’ and the principle of agglomeration, which states that if I ought to do A and I ought to do B, then I ought to do A and B. This troubling apparent consequence of moral pluralism must, however, be qualified by a number of observations. First, as Michael Stocker has observed (1990), the premise that statements about moral value are always act evaluations is an unvindicated assumption of much modern moral theory, yet moral pluralism only leads to moral dilemmas if this assumption is granted. There might be a number of true moral descriptions of a situation, emphasizing different moral considerations present in it. Any one of these might well on its own give rise to an ‘ought’ statement, but given the presence of other moral considerations it may give rise only to what Ross has called a *prima facie* obligation. As the latter are not directly action-guiding, they need not conform to the strictures of deontic logic. Second, certain axioms of deontic logic might actually embody controversial first-order moral propositions. The fact that they conflict with the hypothesis of moral dilemmas does not therefore automatically place the burden of proof upon defenders of the latter. Third, the reality of moral dilemmas need not, as philosophers such as Bernard Williams (1965) have suggested, put paid to all attempts to rationally order our, at times conflicting, moral values. There are reasons supporting both sides of a moral dilemma, and the presence of a moral dilemma, rather than signalling the necessary end of moral inquiry, can point to the need to undertake inquiry into these reasons in a more fine-grained manner. Moral pluralism involves the denial of the existence of a supreme value from which all others might be derived; it does not entail incommensurability, the view that moral considerations cannot be compared and ranked. Thus, for example, there may be rational priority rules allowing us to order the claims of different moral values.

3 Moral pluralism and political philosophy

The plurality of moral values can manifest itself in a number of different ways. Most relevantly from the point of view of political philosophy, it can involve the existence within a society of a number of equally acceptable moral forms of life. This form of social pluralism poses a set of challenges for political philosophers, suggesting that there may be no simple way of adjudicating conflicts between adherents of equally admirable moral forms of life, or of engaging in the interpersonal welfare comparisons often seen as necessary for the formulation of theories of distributive justice. Moral pluralism has been seen by many philosophers, including John Rawls (1971), Thomas Nagel and Charles Larmore (1987), as calling for the liberal doctrine of state neutrality, the view that particular conceptions of the good ought not to be invoked in the formulation of public policy.

Moral psychology

Moral psychology as a discipline is centrally concerned with psychological issues that arise in connection with the moral evaluation of actions. It deals with the psychological presuppositions of valid morality, that is, with assumptions it seems necessary for us to make in order for there to be such a thing as objective or binding moral requirements: for example, if we lack free will or are all incapable of unselfishness, then it is not clear how morality can really apply to human beings. Moral psychology also deals with what one might call the psychological accompaniments of actual right, or wrong, action, for example, with questions about the nature and possibility of moral weakness or self-deception, and with questions about the kinds of motives that ought to motivate moral agents. Moreover, in the approach to ethics known as 'virtue ethics' questions about right and wrong action merge with questions about the motives, dispositions, and abilities of moral agents, and moral psychology plays a more central role than it does in other forms of ethical theory.

1 Psychology and the possibility of morality

We can divide the main traditional concerns of moral psychology as a distinctive philosophical discipline into questions about the psychological assumptions necessary to the validity of morality, or moral rules, in general, and questions about the psychological concomitants or underpinnings of particular actions evaluated either as good/right or as bad/wrong. The question of whether human beings have free will or freedom of choice (see Free will) naturally falls within the first of these areas. If human beings lack free will, then, it has over the millennia typically (though not universally) been assumed, they cannot be held responsible for their actions and cannot be bound by moral obligations any more than are animals or small children. Thus those who have systematically elaborated one or another view of moral right and wrong have usually thought it necessary to defend, or at least explicitly assume, the existence of human free will, or freedom of choice.

In the first instance this standardly involves saying something about free agency in relation to universal causal/nomic determinism. If the world is universally governed by causal or physical laws, then it is unclear how anyone could possibly have behaved otherwise than they in fact did, and so have been responsible for what they did. So defenders of (objective) morality typically feel called upon either to argue that human beings are in important ways not subject to iron-clad causal determination, or else to show that causal determinism does not in fact deprive us of free will (see, for example, Watson 1982; Determinism and indeterminism).

Another metaphysical or quasi-metaphysical issue that looms large in moral psychology concerns the human capacity for morality. Most moral codes and moral philosophies require, for example, that people occasionally put aside self-interest in the name of honour, fairness, decency, compassion, loyalty or the general good. But if one believes in psychological egoism, one will hold that people lack the capacity for these forms of self-sacrifice, and it then becomes problematic whether human beings really have the obligations that various non-egoistic moral views/theories claim that they do (see Egoism and altruism).

But even if one rejects both psychological and ethical egoism (for example, Butler 1950), there are moral-psychological issues about how much morality can fairly be demanded of people. These issues arise especially in connection with utilitarianism (see Utilitarianism) and Kantianism (see Kantian ethics). Utilitarianism is usually stated in a 'maximizing' form that treats it as a necessary and sufficient condition of right action that one do the best/most one circumstantially can to advance the happiness of humankind (or sentient beings). But such a doctrine seems to entail that if one is in a position to relieve the suffering, hunger or disease of others, one is morally obliged to do so, even if that means giving up one's own life plans and most of what one really cares about in life. The traditional utilitarian moral standard is thus very demanding, and some philosophers have questioned whether morality can properly, or, one might say, fairly, require so much of people (see, for example, Stocker 1976; Swanton 1993). In particular, it may be wondered whether most people have the capacity to live up to such a stringent morality as is presented by maximizing utilitarianism.

Certain doctrines of Kantian ethics can likewise be seen as going against the grain of human nature or capacities, not by demanding too much of a sacrifice of self-interest, but by laying down rather stringent or narrow psychological conditions for the moral admirability of actions. According to Kant, if one helps someone in need or in trouble out of fellow-feeling or friendship, one's act lacks all moral worth, because it was not performed out of a

sense of duty and respect for the moral law. And many ethical thinkers have either implicitly or explicitly held such a view of moral virtue to be too narrow and out of keeping with realistic human psychology, and have argued that certain primary, immediate or natural motives such as compassion or friendly feeling not only have moral worth, but can often be even more praiseworthy than a cool appeal to duty or to something as abstract as the moral law (see, for example, Martineau 1891; Stocker 1976). But Kantians question the durability and reliability of mere feeling or emotion, and there remains considerable debate in this area (Blum 1980).

2 Psychology and moral judgment

Another topic that has recently occupied moral psychologists and ethicists is the relevance of so-called ‘moral emotions’ to moral judgments. Some philosophers have considered the validity of one or another moral theory to depend, in part, on whether people tend to feel guilty for violating its dictates (see, for example, Williams 1981). But others have held that there are situations where guilt is inevitable, but that that fact constitutes no sort of evidence of wrongdoing. Indeed, it is sometimes argued that the question of whether guilt for some action is *appropriate* or *justified* is separate from the issue of whether that action was actually wrong (Greenspan 1988). (Is it, for example, appropriate to feel guilty about injuries one caused in a traffic accident that was someone else’s fault entirely?) Other philosophers, however, seek to connect the moral emotions with morality by arguing that the seeming *ineradicability* of our emotions of anger and resentment provides some sort of underpinning for human judgments about justice and injustice, praiseworthiness and blameworthiness (see Strawson in Watson 1982; Morality and emotions; Moral sentiments).

In addition, moral psychologists concern themselves with various forms of situational moral failure, such as self-deception and weakness of will (see Self-deception; Akrasia). The very existence of these phenomena is often questioned on grounds of their paradoxical character. If one is motivated to deceive oneself about some difficult matter (for example, the needs of one’s children), how can one possibly succeed unless one knows what it is one has to deceive oneself about - in which case, in what way is one actually deceived? Similarly, if moral weakness, or weakness of will more generally, means allowing anger or passion to lead one to act against one’s better judgment, is it not natural to reconfigure our understanding of what is happening so as to suppose that the reasons for anger or passion warp one’s sense of what really is best (for one) - in which case, in what way has one actually acted against one’s (however momentary) better judgment?

Both weakness of will and self-deception are, therefore, inherently problematic, and moral psychology has sought ways of either making sense of these moral phenomena or showing them definitively to be incoherent and consequently impossible (see, for example, Pears 1984). Either ‘solution’ has bearing on the moral assessment of actions (and desires). If self-deception is possible, what sort of blame attaches to it when it leads to bad consequences (for example, neglect of children)? Should it be counted as a deliberate, intentional act; or it is more like negligence, or heedlessness? But if self-deception is not possible, then what masquerades as such may be more like intentional wrongdoing, and perhaps even more blameworthy, than it initially appears (see Self-deception, ethics of). Then too, if weakness of will is not possible, many cases we are inclined (at most) partially to excuse on grounds of weakness may be cases in which the agent is actually compelled, psychologically, to act wrongly - or else perhaps momentarily ignorant of the difference between right and wrong. Such conclusions are bound to affect the character and/or severity of the blame or punishment directed at those who initially seemed to be acting weakly.

Another set of issues in moral psychology arises within the tradition of moral theory known as virtue ethics, which treats issues of moral psychology as essential to our understanding of right and wrong action (see Virtue ethics). Thus, rather than basing morality on moral rules or on the production of ‘good consequences’, Aristotelian virtue ethics denies the possibility of universal moral rules and thinks of the virtuous individual as someone who intuitively perceives what is right or noble in various situations and, fairly effortlessly, acts accordingly. To that extent, the Aristotelian tradition in virtue ethics approaches the idea of moral rightness in some measure indirectly, by focusing on the character, habits and abilities of the virtuous individual who tracks rightness in thought and actions (see Feminist ethics).

In addition, there is a more radical tradition of virtue ethics in which the moral evaluation of actions and moral rules is directly derived from characterizations of good and bad motivation and how these may be expressed or realized in someone’s actions. Perhaps the best-known historical example of such an approach can be found in

Plato's *Republic* (Book IV), where it is said that good actions are those that enhance or support the health and harmony of the soul (see Plato §14).

A more recent and 'purer' example (because it does not mention anything like the Form of the Good) can be found in James Martineau's *Types of Ethical Theory* (1885, 1891). Martineau ranks all human motives on an absolute scale - for example, compassion is placed above ambition, the latter above sexual desire, and the latter, in turn, above vindictiveness - and claims that right action is action that comes from the higher or highest motive operating in any given situation of moral choice. This then allows moral rules of thumb to be derived from generalizations about which motives are likely to operate in various morally familiar situations.

These varying virtue-ethical approaches put moral psychology at the very centre of ethics. However, for the foreseeable future, the chief role of moral psychology will probably be as a discipline ancillary to, rather than as the main focus of, moral theory.

Moral realism

Moral realism is the view that there are facts of the matter about which actions are right and which wrong, and about which things are good and which bad. But behind this bald statement lies a wealth of complexity. If one is a full-blown moral realist, one probably accepts the following three claims.

First, moral facts are somehow special and different from other sorts of fact. Realists differ, however, about whether the sort of specialness required is compatible with taking some natural facts to be moral facts. Take, for instance, the natural fact that if we do this action, we will have given someone the help they need. Could this be a moral fact - the same fact as the fact that we ought to do the action? Or must we think of such a natural fact as the natural 'ground' for the (quite different) moral fact that we should do it, that is, as the fact in the world that makes it true that we should act this way?

Second, realists hold that moral facts are independent of any beliefs or thoughts we might have about them. What is right is not determined by what I or anybody else thinks is right. It is not even determined by what we all think is right, even if we could be got to agree. We cannot make actions right by agreeing that they are, any more than we can make bombs safe by agreeing that they are.

Third, it is possible for us to make mistakes about what is right and what is wrong. No matter how carefully and honestly we think about what to do, there is still no guarantee that we will come up with the right answer. So what people conscientiously decide they should do may not be the same as what they should do.

1 Realism, objectivism, cognitivism

These three terms are hard to keep separate, but it is worth the effort. Cognitivism is the claim that moral attitudes are cognitive states rather than noncognitive ones. The distinction between cognitive and noncognitive states is not clear; the best way of drawing it is by appeal to the distinction between two 'directions of fit'. Beliefs, which are the paradigm examples of a cognitive state, have one direction of fit; desires, which are the paradigm examples of a noncognitive state, have the other. A belief, that is, has to fit the world; the world is given, as it were, and it is the belief's job to fit that world, to get it right. A desire is not like that; the desire's job, if anything, is to get the world to fit it, to make things be the way it wants them to be. Crucially, a desire is not at fault if things are not as it wants them to be; a belief is at fault if things are not as it takes them to be. The question whether moral attitudes are cognitive states or noncognitive ones is the question whether they have the direction of fit of a belief, or that of a desire. They could, of course, be complex states with a mixture of both; but noncognitivism is the view that moral attitudes have either wholly or partly the direction of fit of a desire. This is normally expressed more briefly as the view that moral attitudes either are or at least contain desires; to think an action right is a sort of 'pro-attitude', and pro-attitudes are wantings (see Belief; Desire; Moral Judgment §1).

Realists, believing that there are distinct moral facts, are likely to be cognitivists, since the appropriate attitude to a fact is belief rather than desire. It is for this reason that the opposition to realism is normally called 'noncognitivism'. Realists, holding there to be moral facts, maintain for that reason that moral attitudes are beliefs; noncognitivists, holding that moral attitudes either are or include desires, claim for that reason that there are no facts to be the objects of those attitudes.

Objectivism is harder to distinguish from realism, since the two are very closely linked. Objectivity is something to do with independence from us. Realism, as characterized above, combines three theses: a distinctness thesis, a metaphysical thesis and an epistemological thesis. The metaphysical thesis is the claim that moral facts are objective. If moral facts are independent in some way, what exactly is it that they are independent of? To say 'independent of us' is little help at best, and straightforwardly wrong at worst. Moral facts concern agents and actions, which are human matters, and so they are not completely independent of us; if we were different, different actions would be wrong. The phrasing used above, 'independent of any beliefs and thoughts we might have about them', attempts to be more precise, at the cost of excluding too much. Is the limitation involved in 'about them' justified? If not, what other limitation would be better? This matter is very difficult to resolve (see Values; Objectivity).

Realism, on this showing, is a complex of claims. The distinctness claim carves out a distinctive subject matter for

ethics. The independence claim tells us something about the sort of fact that ethics is concerned with. The epistemological claim tells us that we have a less than perfectly secure grip on those facts. Moral realists have, however, generally been willing to say that we are capable of moral knowledge, even if we do not achieve it very often. They would all agree that are we capable of justified moral beliefs (if they are cognitivists).

Readers should be aware that the characterization of moral realism is a matter of hot debate. In particular, as well as the sort of account offered in the present entry, there is a form of realism that, taking its start from the claim that there are facts of the matter in ethics, and so moral truths, holds that there must therefore be ‘truth-makers’ - things that make the truths true. In the moral case, what makes moral truths true must be the possession of moral properties by suitable agents and actions. Realism, so understood, is the commitment to moral properties and relations as no less ‘real’ than other properties. It is possible, however, to combine these two strands of realist thinking without strain.

2 Arguments for realism, and an outline of its history

Corresponding to the three elements of realism, there are three things commonly urged by realists in favour of their position. In different ways, they all suggest that we should take seriously the way things initially appear to us. Realists try to hold that things are as they appear, despite noncognitivist arguments that they cannot possibly be. This is sometimes called ‘the appeal to phenomenology’.

First, realists claim that moral thought appears to have its own subject matter, distinct from science and all natural inquiry. Second, they argue that moral judgment appears to be an attempt to determine a matter of fact that is independent of any beliefs we might have about it; the fact is one thing, and what we think about it another. Third, realists hold that moral judgment presents itself to the judger as risky and fallible. When facing a difficult choice, especially, we have a sense of thin ice; we know that, with the best will in the world, the view we come to may be wrong. Only the second two of these three claims may properly be termed ‘phenomenological’.

Most moral theorists have been realists, from Plato and Aristotle through Price and Hutcheson to Sidgwick and Mill, and then, in the twentieth century, to Moore and the intuitionist tradition (see Intuitionism in ethics). It is the opposition to realism that needs to be documented. Here the patron saint of noncognitivism is Hume, whose work flowered, though altered in many respects, in the noncognitivist tradition of Stevenson, Ayer and Hare (see Emotivism). Leading contemporary noncognitivists are Blackburn and Gibbard.

Advances in the philosophy of language, philosophy of mind and philosophy of science in the 1960s and 1970s persuaded many that the noncognitivist arguments against realism, which had dominated the intellectual scene since 1930, were less powerful than they had appeared (see Analytic ethics §2). Two quite distinct forms of moral realism emerged, American and British. (This means only that most proponents of the first form are American, and most proponents of the second are British.) In the next two sections, the differences between these two positions will be charted in three areas: metaphysics, epistemology and theory of motivation.

3 American moral realism

Metaphysics. American moral realists are naturalists: they suppose that moral facts are either natural facts or configurations of natural facts (see Naturalism in ethics §1). As suggested in the initial summary, it is possible that the fact that if I do this I will have helped someone and harmed nobody else just is the fact that I ought to do this action. Perhaps, however, the moral fact is more complex than this natural fact (and than any other single natural fact), without this meaning that it is not some combination of natural facts. If so, those natural facts will have to be combined in the right sort of way - in the sort of way that they are here - if they are together to make the moral fact that I ought to do this action. Then the moral fact will be identical with this configuration of natural facts.

This form of naturalism in ethics is often, though not always, accompanied by some form of consequentialism. A certain sort of natural fact is a moral fact because there is a relation between that fact and certain consequences (see Consequentialism). Naturalism in ethics is now a live option again because of a growing sense that G.E. Moore’s ‘open question’ argument is flawed (see Moore, G.E. §1).

Epistemology. American moral realists, seeing moral facts as natural facts, suppose that they are knowable in whatever ways natural facts can be known, including science. To identify those facts as moral facts, we will need

to combine the best scientific theory with the best moral theory.

Theory of motivation. How is it possible to reconcile the claim that moral facts are natural facts with the widespread sense that moral facts have an intrinsic authority - that they make demands on us to which we should respond, whatever our personal choices and preferences? This ‘intrinsic authority’ is hard to understand in any detail. Perhaps the best attempt is Kant’s distinction between categorical and hypothetical imperatives (see Kant §1; Kantian ethics). Moral imperatives such as, ‘Help those less fortunate than you’, are categorical, in the sense that one cannot escape their relevance to oneself by saying, ‘I just don’t care very much about that sort of thing’. By contrast, a hypothetical imperative such as, ‘Use fresh eggs to make an omelette’, has no grip on those who just do not care about how their omelettes taste.

However we understand it, the idea of the authority of moral facts does not sit easily with ethical naturalism. Natural facts, however configured, do not seem able to have any such authority over the will (see Moral motivation §§1-2). American realists generally respond to this by doubting the claim that any fact could have that sort of authority. The world, whether in its moral or its more obviously natural clothes, is one whose grip on us depends on our bringing to it a sort of moral concern (which will have been the product either of evolution or of education). If we lack that concern, we will be unmotivated by moral distinctions, even though we will be still perfectly capable of discovering which actions are right and which are wrong. To know the right is one thing, and to bend one’s will to it another. Moral judgment is cognitive; it is the discovery of facts. But facts are motivationally inert; whether one is motivated by them depends not so much on them as on what one cares about. So moral imperatives are hypothetical, despite appearances.

In these thoughts, American realists adopt what is sometimes called a ‘Humean’ theory of motivation. Neither belief nor desire alone can lead to action; only a combination of the two can do that. (For an action we need two mental states, one with each direction of fit.) Moral facts are the objects of belief. No such belief can motivate alone; for there to be an action, the agent must have some desire or preference as well as the belief. Moral facts cannot motivate in their own right, therefore; their ability to make a difference to how we act depends upon the independent contribution of a desire. This being so, they cannot have such a thing as an intrinsic authority over us; for whether they can make a difference to how we act depends on something over which they have no control (see Practical reason and ethics§2).

4 British moral realism

The British variety of moral realism denies everything that the American variety claims.

Metaphysics. British moral realism is non-naturalist: moral facts are not natural facts, nor are they are natural configurations of natural facts. They may be non-natural configurations of natural facts, but that is another matter. Natural facts are relevant to moral ones, of course, since they are the reasons why actions are right or wrong. It follows from this that any two situations that are naturally indistinguishable must be morally indistinguishable (see Supervenience). But this sort of supervenience is a far cry from any identity between the natural and the moral.

In terms of the characterization of moral realism given earlier, the British thus attribute far greater distinctness to moral facts, considering them to be metaphysically distinct from natural ones. The Americans have a harder task in showing what is distinctive about the moral, though not an impossible one. They can say, for instance, that moral facts are distinguished by their subject matter, or by the sort of configuration of natural facts that they are.

Epistemology. If moral facts are not natural facts, the normal methods of finding out how things are will not suffice for the discovery of the moral. Admittedly, British realists have been prone to talk of seeing that an action is right. But it appears that they mean by this neither that rightness is visible, nor that there is a moral sense in addition to the normal five senses. Talk of seeing that the action is right is intended to echo Aristotle’s remark that right and wrong are not matters of rules so much as of the nature of the case before us, and that to discern what is right we have to concentrate on the details of the present situation (see Virtue ethics §6). They deny, therefore, that moral judgment is a matter of subsumption, of bringing the present case under some moral rule. Moral judgment is the application of concepts, but those concepts are not rules. Indeed, it is characteristic of British realists to be sceptical about the very possibility of moral rules or principles. For them, moral judgment is a matter of recognizing the reasons for action as they present themselves in the present case, and responding to them as such (see Universalism in ethics §3; Logic of ethical discourse). This sort of recognition is not perceptual, but it is

cognitive and practical at once - for what one is recognizing is a reason for action, that is, a normative state of the world.

Theory of motivation. American realists are ‘externalists’ about moral judgment. They hold that the ability of a moral judgment to motivate, that is, to make a difference to how one acts, is dependent on the presence of a quite different mental state, namely some sort of desire. British moral realists are generally ‘internalists’, holding that a moral judgment motivates in its own right, and does not get its ability to affect action from a desire that is present at the same time (see Moral motivation §1). To make this out, they have to reject the standard Humean picture of motivation, though they do not agree among themselves about quite how to do this. Wiggins (1987) and McDowell (1978) hold that action does require a combination of belief and desire, but that in the moral case it is belief that leads and desire that follows. Dancy (1993) suggests that it is belief alone that motivates, since mere recognition of relevant reasons should be enough for action; he sees desire as a state of being motivated (by the reasons), not as what motivates. Either way, the suggestion that there are genuinely normative and non-natural facts is combined with the claim that recognition of these facts motivates in its own right, in a way that is not dependent on the presence of an independent desire.

This raises problems. The first is that Humeanism is more or less received wisdom; so the British are fighting an uphill battle in rejecting it. The second is that it is very hard to make sense of the idea of a state of the world, or fact, that stands in some intrinsic relation to the will. It is normal to think that facts are motivationally inert; to recognize them is one thing, and to bend the will to them another. The British hold that the response to the fact, which we call recognition, is itself motivational. The preferred way of doing this is by appeal to the ‘dispositional conception of value’ (see McDowell 1985). This conception is inspired by a supposedly similar dispositional conception of colour: a red object is one that is disposed to cause in us a characteristic sort of experience (see Colour, theories of §2). Similarly, a valuable object is conceived as one which is disposed to elicit a certain response from us, an inclination of the will. As such, it is not totally independent of us, since it consists (at least partly) in a certain relation to us; and this means that it is not fully objective, if objectivity is to be understood in terms of independence from us. But it is still objective in a weak sense, since value can still be conceived as there for us to recognize and there whether we recognize it or not (see Value, ontological status of).

There are two difficulties with this appeal to dispositions. The first is that the analogy with colours is hotly disputed. The second is that, in order to keep values in the world, their objectivity has had to be diminished. For some, this weaker conception of objectivity is hardly to be distinguished from subjectivity.

5 Realism and minimalism

In this entry, realism has been seen as a combination of three distinct theses. But there is an alternative account of what realism is that sees it as nothing more than a claim about truth. The realist, on this account, holds that moral statements are capable of truth, and indeed that some are true. If we say this, we can still distinguish between realism and objectivism in ethics. Realism is the claim that moral judgments are sometimes true; objectivism is the claim that the sort of truth they have is objective truth.

We can distinguish two sorts of opposition to this form of realism. The first accepts that moral statements are capable of truth, but holds that all are false (see Moral scepticism §3); the second holds that truth is not the appropriate form of success for a moral judgment, and that we would do better to think of them as sincere or insincere, or as more or less well connected with other judgments, or as ones that we ourselves would agree with. One should not try to combine these two sorts of opposition.

Crispin Wright (1992) has suggested that, if this is what is at issue between realism and noncognitivism, the matter will be quickly resolved in favour of realism. In his view, the mere fact that moral discourse is assertive, and that moral utterances are governed by norms of warranted assertibility, is enough to establish that we make no mistake in calling some true and others false. The question should not be, then, whether moral judgments are capable of truth, since everyone really admits that they are. Instead, the debate about realism should focus on other questions. According to Wright, among these questions are:

(1) Is it a priori that differences of moral opinion can only be explained in terms of divergent input, unsuitable conditions or malfunction (such as prejudice and dogma)?
(2) Do the supposed moral facts serve to explain anything at all? Suppose that they explain (some of) our moral

beliefs. Do they explain anything else in a way that is not mediated by our beliefs? That is to say, do moral facts directly explain anything about how the world goes?

Wright suggests that we only get a ‘full-blooded’ moral realism if our answer to these questions is ‘yes’. There will, therefore, be degrees of realism, and in a way the question is not whether we should be realists, but what sort of realists we should be. How far should our realism go?

6 Arguments against realism

Since realism comes in different forms, arguments against it are more likely to attack some particular form than to attack realism as such. The main difficulties for the American and the British realist schools have already been mentioned. In both cases they were metaphysical. The Americans have difficulty in keeping moral facts both natural and moral. The British have difficulty in explaining how the world can be other than ‘motivationally inert’.

The two general challenges to realism that are most often mentioned are those made by John Mackie and Gilbert Harman. Harman (1977) asks what, if anything, is explained by moral facts that cannot be equally well explained by moral beliefs. If moral belief alone is enough for all such explanations, why suppose that the facts exist in addition to the beliefs? The facts appear to be explanatorily redundant. We might suggest that at least the facts explain the beliefs, but Harman replies that the beliefs can be equally well explained in other ways, for example, by appeal to upbringing and education. This leaves the facts explaining nothing; they are mere metaphysical danglers, hanging in the air and not related to anything else at all. We are better off without such things. (This is different from Wright’s view above, because Wright allows that moral facts could explain moral beliefs; he only asks whether they could explain anything else ‘directly’.)

Mackie (1977) suggests that values, if they existed, would be very peculiar things, unlike anything else in the universe; so queer are they that, if they existed, we would need a special faculty of moral perception or intuition to perceive them. Their queerness lies in the idea that an objective value would necessarily be pursued by anyone who recognized it, because such values have ‘to-be-pursuedness’ built into them. Even if such things are possible, which nobody influenced by Hume would allow, something of that sort is of a different order from anything else with which we are acquainted.

Mackie also asks about the supposed relation between moral facts and natural facts. We ordinarily say, for instance, that an action was wrong because it was cruel. But ‘just what *in the world* is signified by this "because"?’ (1977: 41; original emphasis). Not only is there the wrongness and the cruelty, but also a totally mysterious ‘consequential link’ between the two.

These arguments of Mackie’s are answered in different ways by the different varieties of realism. The Americans deny the possibility of ‘to-be-pursuedness’; the British admit it, but try to explain it by appeal to the dispositional theory of value. As for the mysterious ‘consequential link’, both sides would, in their different ways, try to say that the wrongness is somehow ‘constituted’ by the cruelty.

Moral relativism

Often the subject of heated debate, moral relativism is a cluster of doctrines concerning diversity of moral judgment across time, societies and individuals. Descriptive relativism is the doctrine that extensive diversity exists and that it concerns values and principles central to moralities. Meta-ethical relativism is the doctrine that there is no single true or most justified morality. Normative relativism is the doctrine that it is morally wrong to pass judgment on or to interfere with the moral practices of others who have adopted moralities different from one's own. Much debate about relativism revolves around the questions of whether descriptive relativism accurately portrays moral diversity and whether actual diversity supports meta-ethical and normative relativism. Some critics also fear that relativism can slide into nihilism.

1 Descriptive relativism

From the beginnings of the Western tradition philosophers have debated the nature and implications of moral diversity. Differences in customs and values the Greeks encountered through trade, travel and war motivated the argument attributed to the sophist Protagoras in Plato's *Theaetetus*: that human custom determines what is fine and ugly, just and unjust (see Protagoras). Anthropologists in the twentieth century, such as Ruth Benedict (1934), have emphasized the fundamental differences between the moralities of small-scale traditional societies and the modern West. For example, many traditional societies are focused on community-centred values that require the promotion and sustenance of a common life of relationships, in contrast to both the deontological morality of individual rights and the morality of utilitarianism that are the most prominent within modern Western moral philosophy. Within this philosophy itself moral diversity is represented by the debates between utilitarians and deontologists, and more recently criticism of both camps by defenders of virtue theory and communitarianism (see Deontological ethics; Utilitarianism; Virtue ethics; Community and communitarianism). Such differences have motivated the doctrine of *descriptive relativism*: that there exists extensive diversity of moral judgment across time, societies and individuals, and that it concerns central moral values and principles.

Critics of descriptive relativism argue that it fails to account for important moral similarities across cultures such as prohibitions against killing innocents and provisions for educating and socializing the young. A relativist response given by Michael Walzer (1987) is to argue that shared norms must be described in an extremely general way and that once one examines the concrete forms they take in different societies, one sees significant variety, for example, in which persons count as 'innocent'. The descriptive relativist might go so far as to assert that no significant similarities exist, but an alternative position is that broad similarities exist that are compatible with significant differences among the moralities human beings have held.

Critics of descriptive relativism also argue that many moral beliefs presuppose religious and metaphysical beliefs, and that these beliefs, rather than any difference in fundamental values, give rise to much moral diversity (see Religion and morality §3). Also, differences in moral belief across different societies may not arise from differences in fundamental values but from the need to implement the same values in different ways given the varying conditions obtaining in these societies. One relativist reply is that while such explanations apply to some moral disagreements, they cannot apply to many others, such as disagreements over the rightness of eating animals or the moral status of the foetus or the rightness of sacrificing an innocent person for the sake of a hundred more.

2 Meta-ethical relativism

The most heated debate about relativism revolves around the question of whether descriptive relativism supports *meta-ethical relativism*: that there is no single true or most justified morality. There is no direct path from descriptive to meta-ethical relativism; the most plausible argument for meta-ethical relativism is that it is part of a larger theory of morality that best explains actual moral diversity.

Critics of meta-ethical relativism point out that moral disagreement is consistent with the possibility that some moral judgments are truer or more justified than others, just as disagreement among scientists does not imply that truth is relative in science. Some relativists are unimpressed by the analogy with science, holding that disagreements about the structure of the world can be sufficiently radical to undermine the assumption that there is an absolute truth to be found. This defence of meta-ethical relativism amounts to founding it upon a

comprehensive *epistemological relativism* that expresses scepticism about the meaningfulness of talking about truth defined independently of the theories and justificatory practices of particular communities of discourse (see Epistemic relativism).

An alternative relativist response is to take a nonrelativist stance towards science and to drive a wedge between scientific and moral discourse. Defenders of such a *morality-specific meta-ethical relativism* argue that scientific disagreements can be explained in ways that are consistent with there being a nonrelative truth about the structure of the physical world while moral disagreements cannot be treated analogously. For example, much scientific disagreement may be traced to insufficient or ambiguous evidence or distortions of judgment stemming from personal interests. Relativists have argued that such explanations will not work for moral disagreements such as the ones mentioned above concerning the eating of animals, abortion, and the sacrifice of an innocent to save more lives.

In offering alternative explanations of moral disagreement, morality-specific relativists tend to adopt a 'naturalistic' approach to morality in the sense that they privilege a scientific view of the world and fit their conceptions of morality and moral disagreement within that view. They deny that moral values and principles constitute an irreducible part of the fabric of the world and argue that morality is best explained on the theory that it arises at least in part from custom and convention. On Wong's view (1984), for example, a good part of morality arises out of the need to structure and regulate social cooperation and to resolve conflicts of interest. Meta-ethical relativism is true because there is no single valid way to structure social cooperation.

Morality-specific relativism divides into *cognitive* and *non-cognitive* versions (see Moral judgment §1). On C.L. Stevenson's emotivist view (1944), for example, moral discourse merely expresses emotion and influences the attitudes and conduct of others (see Emotivism). Cognitive relativists, such as Mackie, Harman, Foot and Wong, interpret moral judgments as expressing belief, on the grounds that moral judgments are often argued or judged true or false on the basis of reasons. Within cognitive relativism, there are those who believe that there is no single true morality because more than one morality is true, and those who believe that there is no single true morality because all are false. J.L. Mackie (1977) represents the latter camp, on the ground that while morality actually arises out of custom and convention, the meanings of moral terms presuppose a mistaken reference to *sui generis* properties that provide everyone with a reason for acting according to morality (see Value, ontological status of). Other cognitive relativists see no need to construe moral terms as containing a reference to nonexistent properties and instead tie their cognitive content to certain standards and rules.

According to such a standards relativism, moral language is used to judge and to prescribe in accordance with a set of standards and rules. Different sets of standards and rules get encoded into the meaning of ethical terms such as 'good', 'right' and 'ought' over time, and into individuals, groups, or societies in such a way that two apparently conflicting moral beliefs can both be true. Though under a relativist analysis the beliefs express no conflicting claims about what is true, they do conflict as prescriptions as to what is to be done or as to what kinds of things are to be pursued. The disagreement is purely pragmatic in nature, though parties to the disagreement may not be aware of this if they erroneously assume they share the relevant standards.

Another crucial question for the standards relativist concerns *whose* standards and rules apply when someone makes a moral judgment. Suppose that Jones makes a moral judgment about what Smith ought to do, but that the standards Jones applies to guide his own conduct are not the same as the standards Smith uses to guide hers. One possibility is that Jones uses Smith's standards to judge what she ought to do. Another possibility offered by Harman in some of his writing about relativism is that one must judge others by standards one shares with them. His theory is that morality consists of implicit agreements for the structuring of social cooperation. Moral judgments implying that the subjects have a reason to do what is prescribed make sense only as prescriptions based on what the speakers and subjects (and the intended audience of the judgments) have agreed to do. Other standards relativists observe that people use their own standards in judging the conduct of others, whether or not they believe these others to share their standards.

There are *radical* and *moderate* versions of meta-ethical relativism. Radical relativists hold that any morality is as true or as justified as any other. Moderate relativists, such as Foot (1978), Walzer and Wong (1984), deny that there is any single true morality but also hold that some moralities are truer or more justified than others. On Wong's view, for instance, certain determinate features of human nature and similarities in the circumstances and

requirements of social cooperation combine to produce universal constraints on what an adequate morality must be like. It may be argued, for example, that a common feature of adequate moralities is the specification of duties to care and educate the young, a necessity given the prolonged state of dependency of human offspring and the fact that they require a good deal of teaching to play their roles in social cooperation. It may also be a common feature of adequate moralities to require of the young reciprocal duties to honour and respect those who bring them up, and this may arise partly from role that such reciprocity plays in ensuring that those who are charged with caring for the young have sufficient motivation to do so. Such common features are compatible with the recognition that adequate moralities could vary significantly in their conceptions of what values that cooperation should most realize. Some moralities could place the most emphasis on community-centred values that require the promotion and sustenance of a common life of relationships, others could emphasize individual rights, and still others could emphasize the promotion of utility.

3 Normative relativism

Does meta-ethical relativism have substantive implications for action? *Normative relativism* - the doctrine that it is morally wrong to pass judgment on or to interfere with the moral practices of others who have adopted moralities different from one’s own - is often defended by anthropologists, perhaps in reaction to those Western conceptions of the inferiority of other cultures that played a role in colonialism. It also has application to disagreements within a society such as that concerning the morality of abortion, where the positions of the disputing parties seem ultimately to be based on fundamentally different conceptions of personhood.

As in the case of descriptive and meta-ethical relativism, however, there is no direct path from metaphysical to normative relativism. One could hold consistently that there is no single true morality while judging and interfering with others on the basis of one’s own morality. Wong has proposed a version of normative relativism consistent with the point that nothing normative follows straightforwardly from meta-ethical relativism. Meta-ethical relativism needs to be supplemented with a liberal contractualist ethic to imply an ethic of nonintervention. A liberal contractualist ethic requires that moral principles be justifiable to the individuals governed by these principles. If no single morality is most justified for everyone, *liberal normative relativism* may require one not to interfere with those who have a different morality, though the requirement of noninterference may not be absolute when it comes into conflict with other moral requirements such as prohibitions against torture or the killing of innocents (see Liberalism).

4 Relativism and moral confidence

A reason why relativism has been feared is the thought that it could easily slide into moral nihilism. Could one continue living according to one’s moral values, which sometimes require significant personal sacrifice, if one can no longer believe that they are truer or more justified than other values that require incompatible actions? One relativist response is that one may reasonably question the importance of certain features of one’s morality upon adopting a view of their conventional origin. Consider that duties to give aid to others are commonly regarded as less stringent than duties not to harm them. Gilbert Harman (1975) has proposed that this difference results from the superior bargaining position of those with greater material means in the implicit agreement giving rise to morality. Those with lesser material means may reasonably question this feature of morality, if they are persuaded of Harman’s explanation. Notice, however, that it is not merely the supposition that this feature arose from convention that may undermine one’s confidence in it. With regard to other features of one’s morality, one may adopt a relativist view of them and continue to prize them simply because they are as good as any other and because they help to constitute a way of life that is one’s own.

Admittedly, people who condemn torture and unremitting cruelty as an offence against the moral fabric of the world may possess a certitude not available to relativists and may find it easier to make the personal sacrifices morality requires. Moral certitude has its own liabilities, however, and has itself contributed to the unremitting cruelty that human beings have inflicted upon each other.

Moral scepticism

Scepticism in general is the view that we can have little or no knowledge; thus moral scepticism is the view that we can have little or no moral knowledge. Some moral sceptics argue that we cannot have moral knowledge because we cannot get the evidence necessary to justify any moral judgments. More radical moral sceptics argue that we cannot have moral knowledge because in morality there are no truths to be known. These radical sceptics argue either that moral judgments are all false because they erroneously presuppose the real existence of 'objective values', or that moral judgments aim to express feelings or influence behaviour instead of stating truths. Critics of moral scepticism, in turn, argue that in at least some cases moral judgments aim to state truths, some of these judgments are in fact true, and we have enough evidence to say that we know these moral truths.

1 Types of moral scepticism

Moral scepticism is the view that we can have little or no knowledge about ethics, about right and wrong, good and bad, virtue and vice (see Moral knowledge §3). It is one of a cluster of views that would challenge or limit traditional philosophical accounts of ethics. Moral relativism claims that moral truth is relative to cultural convention or personal commitment (see Moral relativism); moral subjectivism claims that moral truth is determined by the preferences, feelings, and other subjective states of persons; moral egoism is the claim that it is always obligatory to advance one's own interests (see Egoism and altruism). These positions are motivated by some of the same problems about morality that motivate moral scepticism, but they are not properly speaking sceptical positions, since they are all consistent with the claim that we have extensive knowledge of right and wrong, good and bad, virtue and vice.

Theoretically, at least, sceptics about morality can be divided into global sceptics and specifically moral sceptics. That is, some philosophers are sceptical about morality because they are sceptical about everything, claiming that no one has knowledge of morals because no one has knowledge about anything (see Scepticism). Other philosophers claim that we can and do have knowledge of many things, but not of morality in particular. Global scepticism is not of interest here, and in any event has been comparatively rare in the history of philosophy. Specifically moral scepticism has been more common, mainly because of the intractability of some moral disagreements, the difficulty in providing any plausible account of how we could be causally related to the objects of moral knowledge, and the perception that morality suffers badly when compared with natural science, widely accepted as the paradigm of knowledge. Moral sceptics can be divided into total moral sceptics, who claim that we can have no moral knowledge, and partial moral sceptics who claim that we can have knowledge of some aspects of ethics, but not of others (for example, of good and bad, but not of right and wrong).

Moral sceptics may differ in their accounts of why we fail to have moral knowledge, and these differences can be explained in terms of the traditional analysis of knowledge (see Knowledge, concept of). Traditionally, a judgment has been counted knowledge only when it is both true and justified. Thus, moral sceptics generally argue that in ethics (or some aspect of ethics) one or the other of these conditions is unsatisfiable. Some find fault with the justification of moral judgments; others find fault with their truth.

2 The problem of justification

The first sort of moral sceptic holds that we lack moral knowledge because we lack adequate justification for the moral judgments in question. This inadequacy may be characterized in terms of one of the following: (1) A slim evidential basis for moral judgments, comprising, for instance, only empirical and logico-mathematical truths. (2) Limited kinds of inference admitted in moral reasoning, such as deduction and induction. (3) A strong characterization of moral judgments such that if there were any true moral judgments, they would have to be universal, necessary, and action-guiding. (4) Doctrines such as the 'is/ought gap', according to which no good inferences are possible, from the slim evidential basis to strongly characterized moral conclusions, via the limited kinds of inference admitted (see Logic of ethical discourse).

In antiquity, doubts about the adequacy of justification led some to total moral scepticism. Pyrrhonists such as Sextus and Philo argued that one and the same thing appears good to one set of people and bad to another, due to differences in their customs, laws, mythical beliefs, and so on (see Philo of Larissa; Pyrrhonism; Sextus

Empiricus). These appearances are the only justification we have for the moral value of the things in question, but since a thing cannot be both good and bad simultaneously, and since we have no reason to trust one set of appearances over another, no moral judgment has more rational support than its contradictory, and the appropriate attitude toward all moral matters is suspension of belief.

In modern philosophy, doubts about justification have led some to partial moral scepticism. G.E. Moore, for example, held in *Principia Ethica* (1903) that we could have knowledge of the good, and that right actions were by definition those that produced the most good, but that we could not know which actions were right, because we could not know enough about their causal consequences in the distant future (see Moore, G.E. §1). Similarly, it has been argued by W.D. Ross (1930) that we could know the general principles of *prima facie* duty, but we could rarely, if ever, know in particular circumstances which action was our actual duty, because of the moral complexity of every particular set of circumstances (see Ross, W.D.). In both cases, these philosophers hold that we lack moral knowledge simply because we lack the factual or moral information needed to justify the moral judgments in question.

3 The problem of truth

The second, and more radical, sort of total moral sceptic holds that we lack moral knowledge because in matters of morality there are no truths to be known. Some, often called 'noncognitivists', argue that moral judgments have no truth-value, because they do not express cognitively meaningful propositions (see Analytic ethics; Moral judgment §1). Others, often called 'error theorists', hold that moral judgments have a truth-value, but are in fact all false. Noncognitivism and error theory are often classified as 'anti-realist' theories of ethics, since they reject the realist's claim that some moral judgments are literally true, independently of anyone's beliefs or attitudes about them. It should be noted, however, that they are not the only possible anti-realist positions in ethics, and that anti-realism in ethics need not entail scepticism in ethics.

Noncognitivism was perhaps first suggested by David Hume, who argued that morality was the object of feeling not of reason, and that 'when you pronounce any action or character to be vicious, you mean nothing, but that from the constitution of your nature you have a feeling or sentiment of blame from the contemplation of it' (1739/40: 469) (see Hume, D. §4). Following Hume, early emotivists such as A.J. Ayer (1936) argued that moral judgments such as 'Stealing is wrong' cannot be literally true or false, since they express emotions, as in 'Stealing! Boo!', instead of cognitively meaningful propositions (see Ayer, A.J. §5; Emotivism). Later emotivists, such as C.L. Stevenson (1944), argued that moral judgments serve to express the speaker's attitudes and evoke similar attitudes in the hearer, and prescriptivists such as the early R.M. Hare (1952) argued that they are prescriptions, rather than statements of fact (see Stevenson, C.L.; Hare, R.M. §1; Prescriptivism).

Error theory is the claim that all moral judgments are false, because they aim to state facts about good and bad or right and wrong, but that these facts do not obtain because the objective value entities they presuppose do not exist. J.L. Mackie (1977) argues against objective moral values on the grounds that, if they were to exist, they would be utterly unlike any other sort of entity with which we are familiar. Similarly, Gilbert Harman (1977) argues against objective moral facts and properties on the grounds that they play no role in the best explanation of any observations (see Naturalism in ethics §3; Moral realism).

4 Responses to moral scepticism

Thinking moral scepticism an encouragement to immorality, and an outrageous denial of obvious human experience, numerous philosophers have defended moral knowledge from sceptical criticisms of both types. Defences of the justification of moral judgments can be classified as responses to the four factors outlined in §2.

(1) Some have argued for an expansion of the evidential basis so as to include, for instance, moral intuitions or theological information. (Proponents of the method of 'reflective equilibrium' in ethics claim that moral intuitions should be admitted as the data for moral theorizing just as perceptual judgments are admitted as the data for scientific theorizing - see Moral justification §2.) (2) Some have argued for a richer view of the kinds of inference admissible in moral reasoning. (Stephen Toulmin (1970) has argued that the standards of reasoning appropriate for ethics and other areas of everyday life are different from those of the natural sciences.) (3) Others have tried to lessen the distance between premises and conclusion by reducing the content of the moral judgments in need of

justification. (A utilitarian might try to meet Moore's scepticism about right action by redefining 'right' in terms of 'maximal expected utility' instead of 'maximal utility' (see Rationality, practical).) (4) Still others, including many in the Aristotelian tradition, have argued against doctrines such as the 'is/ought gap', by providing examples of valid 'is-to-ought' inferences, or denying the sharp distinction between empirical and moral judgments which such doctrines appear to presuppose (see Logic of ethical discourse §3).

Similarly, defences of the truth of moral judgments can be classified as responses either to noncognitivism or to error theory. Critics of noncognitivism emphasize the similarity between moral judgments and other types of fact-stating judgment, minimize the tension between the fact-stating and action-guiding functions of moral judgments, or highlight the inadequacies of particular emotivist accounts. (Moral philosophers such as Peter Geach (1972) have criticized noncognitivism as unable to account for the meaning of judgments in unasserted contexts such as the antecedents of material conditionals.) Certain philosophers who are widely thought of as noncognitivist, such as R.M. Hare, have worked to reconcile prescriptivism or emotivism with the possibility of true, hence knowable, moral judgments. In his essay 'Objective Prescriptions' (1993), Hare argues that any moral judgment that fully satisfies the requirements implicit in the logical meaning of moral words, and takes into account all the relevant empirical information, may be called 'true', even though prescriptions are not ordinarily thought of as 'stating facts'. Realist critics of error theories, such as David Brink, Geoffrey Sayre-McCord, and Nicholas Sturgeon, play down the differences between moral facts and properties on the one hand, and physical facts and properties on the other, arguing that the former have a legitimate role in the best explanation of moral and other phenomena. Other critics, such as Ronald Dworkin, Thomas Nagel and John McDowell, reject explanatory potency as an appropriate criterion for existence of values. Still others, such as Crispin Wright, argue for minimalist or coherentist accounts of truth in ethics, which allow moral judgments to be true (hence in principle knowable) despite their failure according to more robust correspondence theories of truth (see Moral realism §6).

Moral sense theories

In Leviathan (1651), Thomas Hobbes argued that since good and evil are naturally relative to each individual's private appetites, and man's nature is predominantly selfish, then morality must be grounded in human conventions. His views provoked strong reactions among British moral philosophers in the seventeenth and eighteenth centuries. Moral sense theories comprise one set of responses. A moral sense theory gives a central role to the affections and sentiments in moral perception, in the appraisal of conduct and character, and in deliberation and motivation. Shaftesbury and Francis Hutcheson argued that we have a unique faculty of moral perception, the moral sense. David Hume and Adam Smith held that we cultivate a moral sensibility when we appropriately regulate our sympathy by an experience-informed reason and reflection.

1 The moral sense

Moral sense theory originated in the work of Shaftesbury (1711), as he drew on aspects of the seventeenth-century English rationalist tradition that dealt with the emphasis Hobbes had placed on self-interest (see Shaftesbury; Rationalism). Hobbes (1651) had argued that natural circumstances lead each man to favour his own interests at the expense of more socially-directed affections, and when men enter into the social compact and obey the dictates of morality they do so primarily from self-interested motives (see Contractarianism §2). Following the Cambridge Platonist Henry More, Shaftesbury conceived of the moral sense as a part of intellect. According to More (1667), our 'boniform faculty' distinguishes goodness, discovering in it a 'sweetness and flavour' that in turn induces us to act virtuously. In his *Inquiry Concerning Virtue and Merit* (1711), Shaftesbury combines the notion of an intellectually grounded taste with Locke's notion of reflection, and argues that our moral sense directs reflexive sentiments of praise or censure to the form of virtue or vice in our affections and resolutions, the psychological springs of conduct (see Locke, J. §3; Virtues and vices §2-5). Certain 'pre-conceptions' in the mind guarantee a correct correspondence between the pleasure of moral admiration and virtuous affections. The virtuous agent is one who achieves a balance of the self-interested and social affections. Shaftesbury's argument concerning how we achieve this balance links obligation with self-interest, and is intended to show both that Hobbes was wrong about the weakness of our other-regarding motives, and that self-love obliges us to virtue. The moral sentiments are disinterested evaluations of virtuous and vicious affections. Our moral admiration of our social affections nevertheless enriches the latter, rendering them 'master-pleasures' that govern all our other motives. Moreover, since such pleasures in turn yield the highest 'self-enjoyment', virtuous action undertaken from other-regarding motives provides agents with the chief means for promoting their own interest.

In his *Inquiry into the Original of Our Ideas of Beauty and Virtue* (1725), Francis Hutcheson defended Shaftesbury's views against the criticisms of Mandeville. Hutcheson followed his predecessor in stressing the instinctively reflexive character of our moral sentiments. In employing an empiricist framework and analogizing the moral sense to our physical senses, however, he severed the intimate connection forged by Shaftesbury between the moral sense and intellect. With Locke, he asserted that reason could not be the source of any new ideas, including our moral perceptions (see Locke, J. §2; Moral knowledge §3). Approbation and blame consist in perceptions of pleasure and pain, and these simple ideas are the immediate and necessary responses of our moral sense to an agent's benevolent or unkind affections. We rely on reason to draw inferences about an agent's character and to inform us of the tendencies of the actions and affections that we evaluate morally, but it cannot by itself determine our moral response.

To counter the claim advanced by rationalists such as Clarke and Wollaston that our rational apprehension of goodness obliges us to virtuous conduct, Hutcheson constructed new arguments concerning reason's limits in *Illustrations on the Moral Sense* (1728). He drew a distinction between reasons for approving or blaming and reasons for acting, while showing that both presuppose our affective nature. In his account of justifying reasons, he acknowledged that we need to justify our particular moral evaluations of actions and characters. Justifying reasons establish the grounds for our approval or disapproval by stating truths about the tendencies of particular actions and motives. Since our approval of benevolence (which Hutcheson regarded as the sole virtue) is uniquely determined by the moral sense, not by the truth of a justifying reason, the justificatory function of such reasons presupposes the moral sense. Exciting reasons are truths concerning the motives of agents, and therefore presuppose affections. Since we may present a justifying reason for approving some action in the distant past that

cannot possibly motivate us, or have exciting reasons for acting in ways that we neither approve nor blame, our reasons for evaluating and our reasons for acting are distinct from one another.

Hutcheson rejected the view of Hobbes and some of the natural lawyers that moral obligation needed the backing of sanctions (see Natural law). He also minimized Shaftesbury's emphasis on the connection between obligation and interest, since it made self-love, not itself a virtuous motive, the sole obligation to virtue. He conceded that there is an interested sense of obligation that concerns the happiness of the agent and presupposes self-love. But he redefined moral obligation to mean the determination of the agent disinterestedly to approve and perform virtuous actions. The unease agents feel if they omit a required benevolent action makes them conscious of their failure with respect to their obligation, without invoking either sanctions or advantage to themselves.

2 Regulated sympathy

In *A Treatise of Human Nature* (1739/40), Hume borrowed Shaftesbury's and Hutcheson's arguments concerning our natural sociality, added to Hutcheson's arguments about the limits of reason, and revised his doctrine of moral obligation (see Hume, D. §§3-4). Both Hume and Adam Smith agreed that our moral sentiments distinguish between virtue and vice, and take as their objects the characters of agents. Aware of rationalist criticisms of the notion of an original moral sense, they appealed instead to the principle of sympathy, regarding it as the foundation for a moral sensibility that is essentially social in character, and requires cultivation through education and experience.

In an important concession to Hobbes, Hume argued that prior to establishing conventions of justice, value responses are relative to each individual in part because of the natural limitations of our social affections and sympathy. In order to resolve the conflicts stemming from each individual's partiality, a more reflective form of interest naturally obliges us to establish rules of justice. Our extended sympathy with all who participate in the convention makes us feel uneasy when others disapprove of our breaking the rules, and this gives rise to our sense of moral obligation. As in Hutcheson's account, moral obligation is connected with our moral sentiments, and does not depend on sanctions. The extensive sympathy underpinning our moral sensibility enables us to adopt general perspectives from which we correct our individual biases and form shared sentiments of praise and blame. Although this more cultivated moral sensibility depends on human conventions, Hume argued that it results from the natural and necessary 'progress of the sentiments'.

Hume distinguished between artificial virtues whose motives arise only when certain conventions are in place, and natural virtues that presuppose natural affections. He also emphasized the importance to us of self-regarding virtues, and argued that we cannot draw a fine line between our approval of virtue and our approval of agents' talents or natural beauty. He agreed with Shaftesbury and Hutcheson that our interested contemplation of the pleasures yielded by moral approval gives us a reason to endorse having a virtuous character. But he also urged that his version of our moral sensibility gains an advantage for virtue because it accommodates our disinterested approval of the experience-informed reason and sympathy that lead us to correct and improve our moral sentiments.

In *The Theory of Moral Sentiments* (1759), Smith refined Hume's account of sympathy, distinguishing between judgments of propriety and judgments of merit. The former arise when impartial spectators sympathize with the agent's motive and approve of its propriety, the latter when they sympathize with both the agent's proper motive and the gratitude elicited by the recipient of the virtuous action. Smith used the distinction to argue for a greater variety of moral sentiments. Hume and Smith argued that our shared moral sensibility enables us to see our conduct and character mirrored in one another's sentiments. But Smith was less sceptical than Hume about the influence of moral judgment on deliberation. When we become the impartial spectator of our own character, we develop a conscience. We can rely on the internal promptings of conscience to guide our own conduct (see Conscience).

Towards the end of the eighteenth century, Reid's connection between moral choice and free will, and the emphasis on the consequences of action for social reform in the utilitarianism of James Mill and Bentham, displaced the moral sense theorists' concentration on our internal sentiments (see Reid, T.; Utilitarianism).

Moral sentiments

Moral sentiments are those feelings or emotions central to moral agency. Aristotle treated sentiments as nonrational conditions, capable of being moulded into virtues through habituation. The moral sense theorists of the Enlightenment took sentiments to provide the psychological basis for our common moral life. Kantian approaches deny the primacy of sentiments in moral personality, and treat moral sentiments as conditioned by our rational grasp of moral principles.

A central issue is whether moral sentiments incorporate moral beliefs. Accounts which affirm a connection with moral beliefs point to the complex intentionality (object-directedness) of such states as resentment or indignation. Against this, some observe that moral emotions may be felt inappropriately.

Of special interest are the sentiments of guilt and shame. These seem to reflect different orientations towards moral norms, and questions arise about the degree to which these different orientations are culturally local, and whether either orientation is superior to the other.

1 Historical perspectives

Sentiments have played various roles in ethical theory. On Aristotle's view, set out in *Nicomachean Ethics*, moral virtue is essentially a condition of the sentiments. It is a state of character, involving a disposition to feel the emotions connected with pleasure and pain in ways appropriate to one's circumstances. Moral virtue is distinguished from other states of character by the fact that the virtuous person's sentiments are responsive to practical reason, which determines what it is right to do or to feel in any given situation. One acquires this state of character through habituation, which refines one's susceptibility to pleasure through repeated performance of virtuous actions, and indirectly affects one's ability to deliberate effectively about the true goods of human life (see Aristotle §23). This complex view of moral sentiments treats them as parts of the nonrational soul, which nevertheless both influence and are influenced by one's capacities for practical reflection; it was opposed in the ancient period by the Stoics, who interpreted sentiments essentially as rational judgments (see Stoicism §19).

A different approach was taken by the sentimentalist theorists of the eighteenth century. Setting themselves against the apparent scepticism and egoism of Thomas Hobbes, these philosophers grounded our autonomous moral faculties not in reason but in the moral sense. The moral sense was interpreted as an innate susceptibility to feel sentiments of approval when confronted with morally virtuous character traits, under conditions of suitably impartial reflection. Virtuous traits were understood primarily in terms of benevolence (or other traits, such as justice, which are useful on the whole); and later proponents of the approach took the moral sense that approves of those traits to rest on a mechanism of sympathetic identification with others (see Moral sense theories).

This conception is like Aristotle's in treating moral sentiments as nonrational phenomena - moral approval cannot incorporate moral judgments, because such judgments would presuppose a rational grasp of moral distinctions of the sort the sentimentalists denied. In this respect, the sentimentalists were very much the precursors of modern noncognitivists, who hold, for instance, that moral judgments serve to express emotions of approval or disapproval (see Emotivism; Analytic ethics §1). In contrast with Aristotle, however, the sentimentalists treated the susceptibility to moral sentiments as an innate part of our common human nature, the emergence of which does not require elaborate habituation; this befits the role of the emotions in moral sense theory, as providing a common psychological basis for moral life (see Morality and emotions §1).

Kant and his followers ground our common moral capacities in reason rather than the emotions. This approach is popularly thought to be hostile to the idea that sentiments contribute positively to the moral life - Kant himself, for instance, notoriously claimed that actions motivated by sentiment have no moral worth (see Kantian ethics). But the denial that moral sentiments play a foundational role in moral thought and motivation does not mean that they have no contribution to make.

Outlined in his *Critik der practischen Vernunft (Critique of Practical Reason)* (1788), Kant's account of the sentiment of respect for the moral law suggests that distinctively moral emotions are structured by our independent rational grasp of moral principles: this approach can be extended to such emotions as indignation, resentment and guilt, which are usually responses to the violation of moral principles. The susceptibility to such moral sentiments

shows that one has internalized moral principles, and it is an important task of moral theory to consider whether the principles it proposes can be so internalized that a society organized around them will be a stable and self-sustaining one.

2 Sentiment and moral belief

A leading issue is whether the moral sentiments incorporate moral beliefs. Philosophers who deny this (such as the sentimentalists, and modern noncognitivists) tend to emphasize the passivity of the moral sentiments, and interpret questions of emotional justification primarily in strategic terms ('Is it good for the agent to be subject to sentiments of this type?'). Kantians and others who take moral sentiments to rest on moral beliefs see greater scope for active control of the moral sentiments, through exercise of our rational capacities for moral judgment; and they treat moral sentiments as open to nonstrategic forms of assessment ('Is a particular moral sentiment really appropriate to its object?').

This difference in approach is difficult to resolve in the abstract: moral sentiments are of many different kinds, ranging from pleasure or approval to such highly structured emotions as pride or regret, and there is no reason to expect any single account to apply to all of them. It is more fruitful to explore the difference with reference to a restricted class of moral sentiments.

Resentment, for instance, is characteristically a reaction to a moral offence, and this aspect of the emotion is naturally accounted for by supposing the emotion to rest on the moral belief that one has been treated wrongly. This moral belief gives the emotion a propositional object, and opens it to assessment in nonstrategic terms ('Was the action I resent really wrong?'). Those who favour this approach can readily explain the difference between resentment and closely related sentiments, such as indignation or disdain, in terms of the moral beliefs that the different emotions incorporate. Opponents point out that resentment is often felt irrationally, on occasions when one does not really take oneself to have been morally wronged. This phenomenon seems hard to reconcile with the claim that episodes of resentment necessarily incorporate a moral belief.

An alternative approach treats resentment and other moral sentiments as refinements of underlying biological syndromes, to be identified not by the moral beliefs they incorporate but by their characteristic causes and behavioural effects. By depriving moral sentiments of their propositional objects, however, this approach seems to deny something essential to states of resentment, namely that they involve a distinctive way of thinking of the person one resents, different from the way one conceives the targets of indignation or anger (which may have similar causes and behavioural effects).

3 Guilt and shame

A different set of questions concerns the degree to which moral sentiments are culturally conditioned (see Moral relativism). Many theories hold that a susceptibility to distinctively moral sentiments such as sympathy or even resentment is built into human nature, providing a common basis for moral discourse and response. But other sentiments have seemed more parochial. Guilt, for instance, is sometimes conceived of as a sentiment available only within cultures whose ethical systems are organized around the notions of law, obligation and individual freedom. In other cultures, where ethical precepts are taken to describe a public ideal of honourable behaviour, shame is the characteristic emotional sanction.

Early statements of the contrast between guilt and shame cultures took the latter to be the more primitive, lacking the resources for fully internalizing moral demands. This 'progressivism' has been reversed in more recent treatments of the distinction, which have seen in shame a moral sentiment that lacks the objectionable aspects of guilt - the metaphysical assumption of absolute freedom before the law, and the pointless cruelty that seems to characterize the bad conscience.

This contrast may be sustained even by those who remain agnostic on the question of whether there are any pure shame cultures. Shame and guilt seem to reflect two different orientations towards moral norms: the personality in which guilt predominates sees them as harsh and punitive requirements, while those in whom shame is the dominant moral sentiment view moral norms as articulations of an ideal way of life, a set of excellences which they aspire to exemplify. (This opposition is sometimes expressed in psychoanalytic literature in terms of a contrast between the super-ego and the ego-ideal; see Freud, S. §§8-9.) Important questions here are whether we

can really do without the guilt-orientation to moral norms, and whether it is as metaphysically and morally suspect as its critics have alleged.

Moral standing

Towards whom is it appropriate to direct fundamental moral consideration? This is the question of moral standing. Many different answers have been offered: all and only those creatures that are themselves capable of extending moral concern and consideration; all humans, whether capable of functioning as moral agents or not; humans plus certain other 'higher' animals (such as gorillas, chimpanzees and porpoises) that can think, reason and be self-aware; creatures capable of feeling sensations such as pain, no matter how otherwise rudimentary their psychological existence; living beings, whether sentient or not; 'holistic' entities such as political states, cultural traditions, biological species, natural ecosystems.

The moral standing issue has great significance both practically and theoretically. Earnestly reconsidering who, or what, counts morally could change what we eat, how we clothe ourselves, the extent to which we spread out over the land. Even those who believe that only humans count morally must still address the theoretically challenging question of what it is about humans that warrants such exclusive concern.

To try to resolve this difficult issue, philosophers have pursued several different strategies. Some work from plausible convictions about particular cases (such as '"Normal" healthy adult humans have moral standing, if anyone does') and then, subject to the demand for principled consistency, try to extrapolate to a more general account of what confers moral standing. Others try to articulate a broad view of the general nature of moral consciousness (as involving, for example, the disposition to empathize with others or promote their good) and work back from that to an account of the most basic conditions of the possibility of being conscientiously considered (for instance, having feelings with which others can empathize or a good which they can take into account).

1 The nature of moral standing

Philosophers often grapple with two major issues. Which considerations would guide and shape a morally decent life, and of whom is morally decent living required? But there is a third very large philosophical concern about the nature of morality: towards whom is it appropriate to direct fundamental moral consideration? This is the issue of basic moral standing: which entities matter morally, not merely for the sake of others, but in their own right?

Essentially the same issue has been formulated in a variety of different vocabularies. What does it take to be a 'moral patient' (as opposed to a 'moral agent')? Who or what is 'morally considerable'? Who can be regarded properly as an 'object' of moral concern (as distinct from the active 'subject' who entertains the concern)? But there are also less appropriate ways to pose the question. Thus it is sometimes rendered as 'Who or what deserves moral consideration?', or 'Who is entitled to such consideration?'. These formulations unduly narrow the scope of the question: being deserving and having a right are only two of the grounds on which beings who matter morally can be taken into consideration for their own sake (see Desert and merit; Rights).

The use of the expression 'moral standing' is modelled on, but in some measure also diverges from, the notion of standing as employed in the context of the law. To have legal standing is to be legally authorized to raise, or have raised on one's behalf, a complaint in court. Thus it is possible to have standing (a) with respect to some legal matters, but not others; and (b) within certain judicial venues only. The notion of moral standing parallels such possibilities: (a) a creature capable of suffering but incapable of thinking and communicating might have a morally significant claim on others not to be treated cruelly but no meaningful claim to 'freedom of thought and speech'; (b) the prospect of being pressed into service as a beast of burden could give an animal moral standing in the 'court' of humanity's conscience; attacks by nonhuman predators in the wild might not. Despite these parallels, moral and legal standing are not equivalent. There can be moral standing without the corresponding legal standing (consider, for example, the emotional support that close friends can rightly expect but not legally compel); and legal standing without fundamental moral standing (consider the fiction of business corporations as legal 'persons').

2 Positions on moral standing

Who, then, has basic moral standing? Many different answers have been offered. At one end of the spectrum is 'all and only those creatures that are themselves capable of extending moral concern and consideration'. But

common sense rejects this answer as too restrictive in scope. Young children are thought to fall within the domain of direct moral concern even before they are able to be morally considerate themselves; perhaps their standing derives from the fact that they are in the process of developing the ability to take others into moral consideration. But the same answer will not do with respect to humans who are profoundly, and permanently, retarded or demented; nor for animals who have desires and feelings, but are not capable of moral understanding and motivation.

At the other extreme, the answer ‘everything has moral standing’ raises at least two difficulties. (1) The greater the number and variety of entities that are to be regarded as having standing, the greater is the potential for serious conflicts of putatively legitimate need and interest. The task of resolving such conflicts justly becomes immensely, perhaps hopelessly, complicated. (2) If even insensate and inanimate entities are to be counted as falling within the domain of basic moral consideration, it remains to be explained what the nature and basis of that consideration could be. Just what ought to be done for the sake of a rock or a mud-hole?

Between these extremes several other answers have been proposed: for example, any creature capable of experiencing sensations such as pain; beings who, though not rational, are more than merely sentient, that is, who have enough psychological structure and complexity to count as ongoing ‘subjects of a life’ or as havers (however nonreflectively) of reasons; all living beings, whether sentient or not; biological species and/or natural ecosystems; societies, political states, cultures and traditions.

Thus, in trying to clarify who or what has moral standing, we will be prompted to investigate other difficult issues: What is it to be a moral agent - is it to be the conscious and self-conscious subject of a life, or to have reasons? What is involved in being sentient and how is sentience different from mere reactivity? What is it to be alive? How is biological life relevantly different from homeostatic mechanism? What is a species, an ecosystem? What differentiates one species from another, one ecosystem from another?

For each putatively relevant criterion (such as rationality, self-awareness, conscience, sentience and life), there are difficult questions as to which beings actually satisfy it: Who or what has the capacity for self-awareness and rational reflection - do porpoises and chimpanzees? Who or what is sentient - are clams and oysters? Could plants, slow-responding though they may be, be said to experience anything? Who or what is alive? Do viruses count? Are ecosystems living (super-) organisms too? Shall we say that the earth, or at least the outer crust and atmosphere known as the biosphere, is a living being (‘Gaia’) in its own right?

Perhaps there is some wisdom in more than one such view. As there are several different dimensions of moral concern, so it might be the case that different kinds of entities warrant different kinds of concern. This possibility is illustrated by Hume’s claim (1751) that while humans must treat animals kindly, they are not required to treat animals in accordance with rules of justice (which for Hume have to do primarily with property and contract) (see Hume, D. §5; Justice). Whatever we may think of the specifics of Hume’s position, the general insight behind it seems plausible. How a morally virtuous human agent ought to treat beings of another kind depends on the nature and capacities of the being in question: towards a sentient creature lacking the capacity to form expectations and harbour hopes, there is a duty to refrain from cruel treatment but no duty to keep ‘promises’; towards a living being incapable of experiencing pain and suffering, there is no duty to refrain from cruel and inhumane treatment, but there may yet be a duty to preserve its life, or the possibility of reproducing its kind.

Thus moral standing need not be all or nothing. Unfortunately, deciding on which entities are to be included within the domain of basic moral consideration does not by itself decide the question of how to resolve conflicts of legitimate need and interest. To help meet this problem, some philosophers argue that in the event of conflict moral priority ought to be given to beings with self-consciousness or with the capacity to reason or to creatures of the same species (or culture or community) as oneself. Other thinkers urge a more egalitarian approach.

3 Theoretical and practical import

The question of moral standing should have profound theoretical significance. Even ethicists who prefer to limit their focus to the domain of humankind must come to terms with the question: what is it about fellow humans that warrants such (exclusive) concern or consideration? Is it because they are capable of having experiences, feelings, hopes, desires? Then it would seem to follow that at least some nonhuman beings ought to be taken into consideration as well. Or is it a matter of ‘species-solidarity’ - the mere fact that we humans are all members of the

same biological species? From this it follows that intelligent beings visiting from another planet would be entitled to conquer and enslave us, or at least to be completely indifferent to how their actions affected us, because we and they are not all members of the same biological species. It seems more plausible to suggest that as thinking, feeling beings, humans do matter morally and hence that it would be unreasonable of other-worldly but morally responsible agents, even those of a different biological species, not to extend to us at least a measure of respect and consideration.

At the same time, the moral standing issue also holds more than purely theoretical interest. Agriculture, urban development, biomedical research, energy technology - these are some of the respects in which human practice could be altered profoundly by earnest reconsideration of who or what has basic moral standing (see Agricultural ethics; Bioethics; Technology and ethics). Even within the human sphere, there are difficult cases to address: future generations (see Future generations, obligations to); the deceased; people suffering from earthquake, famine or persecution, who live in distant places (see Help and beneficence); pre-natal human organisms (see Reproduction and ethics); human beings who are profoundly retarded or demented; and human organisms in a persistent vegetative state (see Life and death §3).

Of course, even if plants, animals, endangered species and ecosystems turned out not to have basic moral standing, many of the same restrictions on human conduct could conceivably be generated by purely ‘anthropocentric’ considerations, such as the concern not to undermine environmental conditions crucial to human survival; the desirability of keeping open the range and variety of humanly valued (emotional, aesthetic and even scientific) experiences; and the importance of reinforcing inhibitions and compunctions (against such factors as cruelty and wastefulness) that humans sorely need to cultivate in their dealings with one another.

Arguments such as these make the moral status of nonhuman entities contingent upon putative facts (psychological and ecological) of human life. Animal liberationists, reverence-for-life theorists, and ‘deep ecology’ advocates typically seek to ground the moral significance of nonhuman entities in properties wholly intrinsic to the entities themselves (see Animals and ethics; Environmental ethics). They dismiss human-regarding defences of respect for nonhuman nature as too limited, uncertain and shallow. Despite the large theoretical gulf that separates the two opposing schools of thought, the extent to which they might nevertheless converge in their specific policy prescriptions remains an open, and largely empirical, question.

4 How to decide moral standing: possibilities and pitfalls

How, then, can we make progress towards resolving this profoundly difficult issue? Philosophers often start with intuitively plausible convictions about particular cases (such as ‘"Normal" healthy adult humans have moral standing, if anyone does’) and then try to extrapolate, subject to the demand for principled consistency, to a more general account of what confers moral standing. Working from the other direction, philosophers sometimes try to trace out the implications of a well-established normative theory. Taking a utilitarian perspective, for example, one might reason that what confers moral standing is the capacity to experience pleasure and pain, or to form preferences whose satisfaction or frustration could be said to matter to oneself (see Utilitarianism). From a Kantian perspective, it might be argued that the only beings who ought to be taken into respectful consideration for their own sake are those who are (actually or potentially) capable of reasoning about what to do and of regulating their conduct accordingly (see Kantian ethics). Somewhere in between, there is the possibility of working back from such ‘mid-level’ common-sense considerations as kindness, fidelity and fairness, to the conditions of the possibility of being thus considered. For example, if there is a duty not to be cruel, then it applies to all and only those creatures who can suffer; if there is a duty to be honest, then creatures who have the capacity to form beliefs and expectations ought not to be deceived and defrauded. A fourth possibility is to articulate a broader, more procedural account of what is involved in being morally thoughtful. For example, moral consciousness seems to involve a willingness (1) to empathize with others, to try to imagine what it is like to be in their position; (2) to take their good or wellbeing into account; and (3) to deal with them in ways that can be justified to them. From these observations it seems to follow that nothing can be treated with morally thoughtful consideration unless there is something it feels like to be that being, a perspective of its own with which to empathize; or unless it has a good or wellbeing that can be taken into benevolent consideration; or unless it has a mind or will that can be respectfully consulted and addressed.

Such approaches are not without their pitfalls. Relying on (1) the paradigm of humanness, we might well be

accused of being anthropocentric, extending moral concern only to those beings that resemble ourselves to a degree sufficient to inspire our parochial interest and concern. Relying on (2) a familiar theoretical approach or on (3) everyday mid-level moral considerations, we run the risk of working from a perspective that is already tailored to an overly narrow conception of the domain of proper moral consideration. But charges of self-bias, anthropocentrism, speciesism and the like cannot be pressed indefinitely without losing some of their force. For suppose it were suggested that a grain of sand has moral standing and that to deny this is only to betray an unduly biased perspective. To respond to this challenge one could reasonably raise any or all of the following questions. What is the perspective of the grain of sand and what would it be like to empathize with it? In what does its good or wellbeing consist? What could count as respectfully consulting or addressing its will, or as justifying oneself to it?

Moralistes

The moralistes constitute a tradition of secular French writing about human nature and political and social behaviour principally in the context of the court and the salon. Their non-systematic observations about mankind are couched in literary forms, such as the maxim and the pen-portrait, appropriate to the social context from which they emerged. The four principal moralistes of the ancien régime *were La Rochefoucauld, La Bruyère, Vauvenargues and Chamfort. La Rochefoucauld's Maximes (1665) constitute a sharp attack on the neo-Stoic moral optimism of the first half of the seventeenth century, and determine self-love to be the mainspring of all human behaviour. La Bruyère's Caractères (1688) is a more diverse work in both form and content: it contains a satire of the follies and vices of his age, as well as vivid pen-portraits. There are implicit contradictions in the moral norms governing this often indignant denunciation of men and society. Vauvenargues, writing some fifty years later, expresses more confidence in human nature, rehabilitating the passions and arguing for the moral value of self-love of a certain kind. This optimism is not shared by Chamfort, whose Maximes et pensées (1795) reverts to the cynical tone of his seventeenth-century predecessors in the genre. These writers do not attempt to systematize their thoughts, and they choose to express themselves in urbane and witty ways rather than in sober prose, but they carry out the Cartesian programme of employing 'common sense' and native intellectual powers to the end of uncovering aspects of human nature and behaviour accessible to observant people free from moral or religious preconceptions.*

1 'Moralistes'

The term 'moraliste', which first became current in its modern sense in the mid-eighteenth century, designates thinkers (usually not professional philosophers) who study humanity in a non-systematic, secular way, examining personal, social and political conduct with clear-sightedness and objectivity. In some accounts, this predominantly French tradition is said to stretch from Montaigne in the late sixteenth century to Paul Valéry in the twentieth; but it is more usual to see the heyday of the moralistes as the *ancien régime*, and especially the latter half of the seventeenth century. The practice of setting down dispassionate observations about human motives and behaviour in non-specialized terminology has very diverse roots, among which are: the educational exercise of keeping commonplace-books, in which students recorded pithy sentences from their reading; the practice of dialectical reasoning, which included the collection of points or *loci* to support a given conclusion; the existence of popular collections of proverbs, adages, and apophthegms; the habit of extracting realistic political doctrine in the form of precepts from historical writing and debunking the claims of Stoic virtue, whose most notorious practitioner was Machiavelli (see Stoicism); the development of manuals of civility and books of advice to courtiers based not on the morality of behaviour but its practical benefit to the individual and to society as a whole; the cult of witty conversation at court and in the salons; and finally, the invitation of Descartes to all people to examine their own thoughts with the free use of their innate powers of reasoning.

The mode of writing most associated with the moralistes is the maxim, although they also express themselves in short moral reflections and essays. The maxim can be distinguished from the proverb and apophthegm by its greater abstraction and elegance of form although, like the proverb, its author is not identified and it is given no specific context in time or place. It very often embodies a paradox, either of the kind which refutes a commonly received opinion about human nature and institutions (women are said to be better than men, for example, and tyranny than monarchy), or it is a paradox of a linguistic or terminological kind which breaches the rule of non-contradiction (such as the claim that it is foolish to be wise). In either form it is designed to surprise readers, by revealing to them some hitherto unnoted aspect of human society or by unmasking one of the ways in which human beings are dupes of their own nature. The more discursive literary forms adopted by moralistes do not necessarily have all these features, but there is the same combination of neutral, dispassionate, anonymous, general presentation with an implied social context of witty, secular, non-pedantic, urbane conversation. The four principal moralistes are usually said to be La Rochefoucauld, La Bruyère, Vauvenargues and Chamfort: all were either members of the highest level of French salon and court society, or its clients.

2 La Rochefoucauld

François, duc de La Rochefoucauld (1613-80) was born into the highest aristocracy. After a career in the army,

followed by hectic involvement in domestic political intriguing, he suffered a short period of banishment from Paris and the court before returning to both in the 1650s. His *Réflexions ou sentences et maximes morales (Reflections or moral aphorisms and maxims)* had its first authorized edition in 1665, having been produced in consultation, if not collaboration, with Jacques Esprit and Mme de Sablé: its fifth, much emended, edition appeared in 1678. The preface to the second edition of the work makes explicit its secular nature, but the Augustinian (or Jansenist) tone and vocabulary of much of the work are manifest. The preface also invites the reader to engage in a search for coherence which the form of the maxim frustrates, through its use of qualifying adverbs (often, usually, rarely, sometimes, mostly), its ambiguous syntax and inconsistent or vague use of terms, and its changes in tone, which varies from the cynical to the urbane; but a certain number of conclusions can be drawn from this deliberately disordered collection of discrete aphorisms. It is uniformly anti-Stoic: the heroic ethic which had dominated French literary and moral writing in the first half of the seventeenth century is systematically debunked. Human claims to know themselves through the exercise of reason, human contempt for death and for fortune in all its guises, human mastery over the will and passions, human love of virtue for its own sake, are all shown to be illusory or false; the subjection to their *amour-propre*, to their physiological nature and to the demands made upon them by the social environment in which they live are amply demonstrated. Much of this material is specific to the cultural context from which it emanates, being the product of a clear-sighted member of a disillusioned generation of aristocratic adventurers living in a society which placed great value on wit and urbanity. Its presentation in the form of aphorisms lends it however that air of universality which is traditionally associated with the classical age in France.

3 La Bruyère

Jean de la Bruyère (1645-96) was a member of the bourgeoisie and a client of the high nobility and of the theologician Jacques-Bénigne Bossuet, whose religious and political views he shared. He published his *Caractères ou les moeurs de ce siècle (The characters or mores of our age)* in 1688, on the coat-tails of a translation of *Characters* by Theophrastus; a ninth, much augmented edition appeared in 1696, by which time an unofficial key to the pseudonymous society portraits it contained had been published. The fifteen, rather disparate sections of the work consist of a mixture of short moral essays, maxims and pen-portraits; they were said by La Bruyère to culminate in the last section which purports to be a refutation of free-thinking, although it is difficult to substantiate, from internal evidence, the claim that such a refutation is the main point of the work.

La Bruyère’s work differs from La Rochefoucauld’s in its broader consideration of society and its preoccupation with writers and literary criticism. There are many apparent inconsistencies in the work: it claims not only to inculcate moral lessons, but also characterizes men as incorrigible; it favours the recognition of personal merit and social mobility in one section, only to denounce violently the social ascension of bourgeois financiers and the abandonment of the old feudal order in another; it strongly defends the use of the classics as aesthetic yardsticks at one point, only to engage in ‘modern’ techniques of literary composition at another. The work may best be viewed as a satire, in which La Bruyère deploys a wide range of rhetorical voices and devices, sometimes presenting himself as a detached, impartial observer, sometimes as a professional writer, sometimes as a representative of the bourgeoisie, sometimes as La Bruyère the oppressed client of the aristocracy; in this way he sets out to elicit a wide range of responses in his readers, ranging from indignation at the manifest injustices of society to detached amusement at its less harmful follies. Except in the rather unsatisfactory last section in which he sets out to prove the existence of God, he chooses to depict vice and folly rather than to enunciate the (often contradictory) moral norms which their denunciation implies. In his pen-portraits, which show him to be a very talented observer and painter of his age, he succeeds in using concrete details to flesh out the sometimes schematic moral character being described. He was one of the great stylists of his day, and a writer committed to promoting the cause of art and artists, but never at the expense of his satirical purposes.

4 Vauvenargues

Luc de Clapiers, marquis de Vauvenargues (1715-47) was, like La Rochefoucauld, a member of the aristocracy who did not receive a formal education but, unlike La Rochefoucauld, he played no part in the court or the salons of Paris; he served for a time as an army officer, before premature retirement and death from ill-health. His *Introduction à la connaissance de l’esprit humain, suivie de réflexions et maximes (Introduction to the knowledge of the human mind, followed by reflections and maxims)* (1746) did not receive the same attention as the works of

La Rochefoucauld and La Bruyère when they were published. In three books he deals with the mind, the passions, and the vices and virtues; his maxims were written very much with La Rochefoucauld and Pascal in mind, but where his predecessors had stressed human's enslavement to passions and the impotence of reason, Vauvenargues claims for humankind a degree of moral autonomy and a capacity for virtue. Passions are not to be seen in exclusively negative terms, but rather as the mainspring of moral thought and action; they are the very sources of intellectual activity, not forces which pervert it. Before Rousseau, he made the distinction between *amour-propre* (self-love) and *amour de nous-mêmes* (love of self), seeing the latter sort of love as compatible with virtue. This anti-Jansenist stance, which Vauvenargues shares with Voltaire and which he derives to some degree from Spinoza, is accompanied by a tolerant Deism, making Vauvenargues representative of his age, and suggesting parallels with the aphoristic productions of Voltaire himself (in his *Dictionnaire philosophique (Philosophical dictionary)* of 1764) and of Diderot (in the more contentious *Pensées philosophiques (Philosophical thoughts)* of 1746).

5 Chamfort

Nicolas-Sébastien Roch (1741-94), alias de Chamfort, has more in common with La Bruyère, being like him a client of aristocratic society and a reputed wit. A fervent supporter of the French Revolution, he none the less became suspect under the Terror, attempted to take his own life, and died shortly thereafter. His *Maximes et pensées, caractères et anecdotes (Maxims and thoughts, characters and anecdotes)* - also published with the ironic title *Produits de la civilisation perfectionnée (The products of perfected civilisation)* - first appeared posthumously in 1795. They claim to steer a middle course between the pessimistic depiction of human nature found in such thinkers as La Rochefoucauld and the optimism of idealist philosophers such as Shaftesbury, but the often cynical or pungent tone suggests more affinity with the former. Chamfort expresses great admiration for English philosophy, and especially Bacon; he recommends a radical inductive approach to social and political philosophy as well as to science, but most of his observations are directed at the corrupt aristocratic society of the last years of the *ancien régime*, and suggest an attitude of resignation rather than revolution, taking particular delight in representing social and political life through the metaphor of the theatre.

6 Conclusion

These moralistes embody a philosophical approach in so far as they set out to liberate themselves from preconceptions and observe humankind in its social and political context impartially; but what they have to say and the forms through which they express themselves are closely linked to their envisaged readership. Even the maxim form, which appears to state abstract, general truths outside any social context, is impregnated with the intention to shock, unsettle and surprise. It is therefore reasonable to claim that moralists reflect the thinking of their day in moral matters, but much less plausible to characterize them as independent thinkers making significant contributions to the history of moral thought.

Morality and emotions

Emotions such as anger, fear, grief, envy, compassion, love and jealousy have a close connection to morality. Philosophers have generally agreed that they can pose problems for morality in a variety of ways: by impeding judgment, by making attention uneven and partial, by making the person unstable and excessively needy, by suggesting immoral projects and goals.

The place of emotions in moral theories depends on whether they are conceived of merely as impulses without thought or intentional content, or as having some sort of cognitive content. Plato argued that emotions form a part of the soul separate from thought and evaluation, and moved, in the course of his writings, from a sceptical view of their contribution to morality to a more positive appraisal. Aristotle connected emotions closely with judgment and belief, and held that they can be cultivated through moral education to be important components of a virtuous character. The Stoics identified emotions with judgments ascribing a very high value to uncontrolled external things and persons, arguing that all such judgments are false and should be removed. Their cognitive analysis of emotion stands independent of this radical normative thesis, and has been adopted by many philosophers who do not accept it.

Modern theories of emotion can be seen as a series of responses and counter-responses to the Stoic challenge. Descartes, Spinoza, Kant and Nietzsche all accepted many of the Stoics' normative arguments in favour of diminishing the role played by emotions in morality; they differed, however, in the accounts of emotion they proposed. Focusing on compassion or sympathy, Hutcheson, Hume, Rousseau, Adam Smith and Schopenhauer all defended the role of some emotions in morality, returning to a normative position closer to Aristotle's (though not always with a similarly cognitive analysis).

Contemporary views of emotion have been preoccupied with the criticism of reductive accounts that derive from behaviourist psychology. By now, it is once again generally acknowledged that emotions are intelligent parts of the personality that can inform and illuminate as well as motivate. Philosophers' views have been enriched by advances in cognitive psychology, psychoanalysis and anthropology. Feminist accounts of emotion differ sharply, some insisting that we should validate emotions as important parts of moral character, others that emotions shaped by unjust conditions are unreliable guides.

1 Morality and conceptions of emotion

Emotions are usually considered to be distinct both from bodily appetites, such as hunger and thirst, and from objectless moods, such as irritation and endogenous depression (see Emotions, nature of). Major members of the class have traditionally been love, anger, grief, fear, envy, jealousy, guilt and pity (compassion) (see Love; Moral sentiments; Rectification and remainders). Some philosophers have adopted an account of these experiences that makes them rather close to appetites after all: emotions are surges of affect or energy in the personality, unreasoning movements that push people into acting without being very much connected to their thoughts about the world. This view is frequently connected to the idea that emotions derive from an animal part of our nature, often by thinkers who do not have a high regard for animal intelligence.

Seen this way, emotions figure in morality only as forces that either advance or impede the purposes of moral judgment or will. They can be trained and to some extent conditioned, but in a relatively mechanical manner. Thus they will never be what makes a virtuous character virtuous, though a virtuous person can take pride in having exercised an appropriate degree of discipline over them (see Self-control; Virtues and vices §3).

Other philosophical theories about emotions hold that they involve interpretation and belief. An emotion such as grief is not simply a mindless surge of painful affect: it involves a way of seeing an object, an appraisal of that object as important, and the belief that the object is lost. Fear involves the belief that bad events are impending, and that one is not fully in control of warding them off. Such theories hold that changes in the relevant beliefs entail changes in emotion: one who learns that danger is not really at hand will cease to fear. When we scrutinize the beliefs involved in the emotions, it emerges that they are of two sorts: beliefs about what is happening in the world (Is the person really dead? Is the enemy really at hand?) and evaluative beliefs (Is the person really worth getting upset about? Is the danger serious?). Many of the evaluative beliefs derive from social teaching, some of it

moral in nature. We learn what insults are worth getting upset about, what losses are serious, what damages are to be avoided.

Seen this way, emotions become intelligent parts of the moral personality, which can be cultivated through a process of moral education (see Moral education §3). Such a process will aim at producing adults who not only control their anger and fear, but experience anger and fear appropriately, towards the appropriate objects at the appropriate time in the appropriate degree. Merely self-controlled persons look to these theorists like those whose moral development is incomplete or imperfect. If we find them hating foreigners, but controlling their behaviour towards them, we will judge that there is some further moral work they should be doing before they can claim to be fully virtuous.

2 Emotions and character-based theories

All moral theories have some occasion to talk about emotions, but some focus on their cultivation more than others. Theories that focus on the calculation of utility will see emotions as forces that either promote or eclipse such calculations and the appropriate acts (see Utilitarianism). Theories that focus on duty can have a substantial place for an account of emotion, since emotions will be seen as motives that either promote or impede action in accordance with duty (see Deontological ethics; Duty). But if the account of duty is not supplemented with an account of virtue, it will not be clear how these motives should be integrated into the personality. Kant's theory of virtue (1797) shows us that a duty-based view need not neglect emotions as elements in virtue (see Kant, I. §10; Emotions, philosophy of §3). Since this theory has a noncognitive conception of emotion, and also a rather negative view of the contributions made by emotion, it gives emotions a rather restricted role; but there is nothing to prevent a virtue-theory such as Kant's from giving more positive attention to the cultivation of emotion.

Theories of character based on Aristotle and other Greek thinkers, however, have been Western philosophy's most substantial sources for thought about the proper cultivation of emotion within morality (see Emotions, philosophy of §2). Aristotle's norm of a reasonable person is one whose character is infused completely by the correct reasons for action, which have shaped all their motives and attitudes. Because he aims to describe the cultivation of a whole person and way of life, rather than simply to prescribe a list of duties, he has ample scope for discussing emotional self-shaping.

3 Ancient Graeco-Roman theories of emotion: Plato, Aristotle, Stoics

Plato argues in the *Republic* that the soul contains three distinct parts: the calculative part, the appetitive part, and the 'spirited' part (see Plato §14). This last part seems to be where Plato locates emotions such as anger, grief and fear. Although his account is cryptic, he suggests that the emotions differ from appetites in their responsiveness to changes in belief, and also in the fact that they are less brutish and more discriminating. But he refuses to construe them as belonging to the 'part' that performs evaluative reasoning. In normative terms, the *Republic* argues that all pity, fear and grief should be prevented from developing by a process of moral education that teaches young people that there is nothing for a good person to fear or grieve over; anger is apparently allowed to remain, but is channelled for military purposes. In the *Phaedrus*, Plato's account of the emotional 'part' seems more positive: focusing on emotions of reverence and awe, he shows how this element in the personality makes a crucial contribution to virtue and understanding.

For Aristotle, emotions are combinations of a feeling of pleasure or pain with a belief (or perhaps a more rudimentary cognitive attitude, a seeing *x* as *y*). Fear, for example, combines painful feeling with the thought that there are bad events impending. The combination is not casual: the pain is pain *at the thought of* that impending danger. Therefore, changes in belief will change emotions. (Aristotle makes these arguments in *Rhetoric*, showing how an orator can manipulate the passions of the audience.) In normative terms, Aristotle argues that the virtuous person is one who has attained balance and appropriateness in emotion as well as action. A person who completely lacked anger at an insult to loved ones, for example, would be culpably deficient; but excessive anger is strongly criticized, and the condition to aim for is 'mildness of temper' (see Aristotle §§22-4).

Epicurus and his school (including the Roman poet Lucretius) presented impressive accounts of several emotions, in particular the fear of death (see Epicureanism §13). They argued that this fear poisons individuals' lives and causes social distress. Since they agreed with Aristotle about its cognitive basis, they argued that it could be

completely removed by teaching people that death is not a bad thing for the person who has died.

The Greek and Roman Stoics were the great passion theorists of antiquity. They produced impressive analyses and taxonomies of the passions, arguing powerfully in favour of the view that they are essentially evaluative judgments that ascribe to things or persons outside our control great importance for our flourishing (see Stoicism §19). This analysis is continuous with Aristotle's, but it goes a step further, denying that there is any bodily feeling over and above the cognition that is essential to the identity of a particular emotion. This apparently counter-intuitive view is rendered plausible by extensive consideration of the power of thought to transform the personality.

One might accept this analysis of emotion and still hold, with Aristotle, that many of the judgments involved in emotions are true and appropriate: when one's child dies, for example, it is right to think that something of enormous importance has been lost. The Stoics, however, held that all the judgments involved in all the passions are false, because all ascribe too much importance to external things and persons, making people dependent on the world for their happiness. To this argument they added several others: emotions weaken the personality, robbing it of force and integrity; they make one prone to excessive and violent acts; and, finally, they are not necessary to motivate good acts, which can be chosen out of duty alone.

Their conclusion is thus that the emotions should be extirpated from human life. Moved especially by the damage done by anger in social life, and convinced that there is no getting rid of anger without getting rid of the attachments to externals that are also involved in love and grief and fear, they came to the radical conclusion that we can stop cruelty and violence only by cultivating utter detachment from everything that used to matter to us. They then strove valiantly to show that we can motivate an active concern for humanity without relying on emotion. Removing emotions is not expected to be like removing false beliefs about more trivial matters: because the evaluations involved are transmitted early through social and parental teaching, they have become deeply habitual, and can be changed, if at all, only through a lifetime of patient effort. Their hope was that as this effort is exercised with greater success, the personality as a whole would become enlightened.

Because their analyses are so compelling and humanly rich, and because they focus with convincing examples on the depredations of emotion in politics, writers such as Seneca and Marcus Aurelius continue to make this radical thesis compelling.

4 Modern supporters of the Stoic normative thesis

The Stoics set the agenda for early modern moral theories of emotion. Most thinkers, though not all, accept some version of the cognitive Stoic analysis of passion; they then differ sharply over the normative thesis. Descartes (1649) modified the Stoic analysis to fit into his divided account of mind and body, but his definitions of the passions are related closely to those of the Stoics; his normative judgments, while not quite as severe, are similar (see Descartes, R. §10).

Spinoza accepted the Stoic analysis and the radical normative thesis, holding, with Seneca, that philosophical therapy can free us from bondage to our emotions (see Spinoza, B. de §9). He gave the normative programme new urgency by insisting that all strong attachments are essentially ambivalent: we love an external person or thing because we find that it assists our efforts to flourish. But anything that can assist us, so long as it is separate from us, can also frustrate us; so all love is mixed with hate. Like the Stoics, Spinoza held that there is a type of joy that is not an emotion in the sense that it is not based on a overvaluation of the significance of externals; it is the contemplative joy with which one regards the deterministic system of the universe as a whole. Like the Stoics, Spinoza identified that order with god; thus the good state is designated the 'intellectual love of god'.

Kant did not accept the Stoic analysis of the passions. Oddly enough, he presented no arguments against it, and no substantial analysis of his own; but he plainly conceived of passions as pre-rational, impulsive and undiscriminating. Thus, the only role he saw passions playing in virtue was a rather mechanical one, as forces that either aid or impede duty. In general, he thought they impede it, and he therefore conceived of virtue as a kind of strength of will, in which the will maintains its control over the potentially disrupting passions.

Kant was well aware of the Stoic normative view. To a great extent he shared it, praising the Stoics for cultivating detachment from passion, and for promoting active beneficence rather than relying on compassionate emotion. But he showed considerable ambivalence, and was unwilling to dismiss compassionate emotion utterly. He understood

that it may be difficult to motivate beneficence without this emotion, that motives of duty by themselves may not suffice. He therefore urged people to seek out experiences in which they will naturally be moved to compassion, so that their beneficence will have the strength of passion behind it.

A surprising ally of the Kantian position was Nietzsche (1881), who objected to pity as an emotion that insults the dignity of the suffering person by implying that this is a person who really needs the things of this world. Equipped with a rather romantic picture of strength and self-sufficiency, Nietzsche believed that the truly strong can rise above life's ills through will, and therefore do not need compassion, grief or fear. Citing the Stoics, Spinoza and Kant as his predecessors, Nietzsche denounced the Christian/democratic tradition of praising compassion as a basic social motive.

5 Modern anti-Stoics: the defence of sympathy

Opposition to the Stoic normative thesis began in the ancient world, with Augustine, who insisted that the goal of self-sufficiency was an inappropriate one for a Christian to pursue. Characterizing the ideal Stoic wise man as obtuse in his detachment from longing and pain, he concluded: 'The fact that something is tough does not make it right; and the fact that something is inert does not make it healthy.' Subsequent Christian views have agreed in characterizing moral error as due to wrongly placed love, and in making love itself an essential ingredient of the cure. Dante's *Divina Commedia (The Divine Comedy)* (1313-21) famously ends with the visionary experience of a harmony of emotion and will. Because emotional error is understood (in an anti-Stoic fashion) to be rooted in the body itself and its sexuality, it is expected that this perfected state will arrive only in paradise, after the purifications of purgatory. Most important Christian thinkers make pity or compassion central parts of Christian life, arguing that these emotions are appropriate expressions of and responses to our vulnerable and imperfect earthly condition.

The eighteenth century saw the flowering of a number of distinct approaches to the sympathetic emotions. Although Christian views did not cease to exert an influence, the notion of original evil was contested increasingly in favour of a view of natural goodness in which basic emotional equipment played a salient role. Hutcheson and Hume made the capacity for sympathy a basic part of human nature (see Hutcheson, F. §2; Hume, D. §3). Hume (1739/40) made many valuable observations about the role of sympathy in motivating moral conduct (see Moral motivation §6). But his conviction that desires and passions are basically noncognitive, and that reasoning is capable only of devising means to ends set by desire, led him to short-change many aspects of the passions that even his own concrete analyses at times acknowledge. Although he connected passions with a characteristic object, he seems not to have treated the connection as essential to the identity of the passion: a passion is simply a particular type of impression caused by the object. Hume's enormous influence has led to the sharp split between passion and cognition that characterizes much modern Anglo-American thought (see Emotions, philosophy of §§3-4).

Rousseau gave the emotion of *pitié*, compassion, a central role in social morality (see Rousseau, J.-J. §4). Describing the education of young Émile (1762), he shows that the experience of being astonished and pained at the pain of another is an essential foundation for all society. Compassion leads us to recognize the vulnerability that all humans share, and to appreciate the pain that disasters of various types cause others. Thus, the emotion leads us to be sceptical of distinctions that situate some people as high above others, their fortunes as vastly more secure. Rousseau evidently thought that emotions, involving complex imagining and thought, convey moral information that it would be difficult to obtain in any other way. Accepting a version of the Stoic idea of original human innocence, he seems to have held that excesses in self-love derive from experience of unequal social conditions.

Adam Smith's *The Theory of Moral Sentiments* (1759) provides one of the modern tradition's most detailed analyses of the moral contributions of emotion. Heavily indebted to the Stoics, Smith develops a richly detailed account of the cognitive content of passions such as anger and sympathy. He differs with the Stoics on the normative question, taking up a more Aristotelian view about attachments to family and loved ones. His device of the 'judicious spectator', modelled on Stoic conceptions of self-scrutiny and conscience, gives the moral agent a way of estimating the point of propriety in passion: we are to ask what a concerned spectator, not personally involved, would feel at the events, and this will help us identify bias and irrationality deriving from our own personal immersion. Despite his positive view of sympathy and other emotions, Smith thought them inconstant and

unreliable as guides to social choice, since he observed that we are most easily moved by events closest to ourselves: an earthquake in China means less to a person than an injury to his own finger (see Smith, A. §§2-3).

Another philosopher who defended the fundamental role of compassion in morality was Schopenhauer (1840). Criticizing Kant, he argued that all genuinely moral action must be grounded in other-directed emotion (see Schopenhauer, A. §6). Imagining compassion as involving a mysterious union of the self with the other, he leaves the reader unclear as to precisely why it is not, therefore, a form of self-concern. Schopenhauer's account had, nevertheless, tremendous influence in a culture dissatisfied with duty-based views.

6 Contemporary views: influences from psychology and anthropology

The middle of the twentieth century saw the rise of noncognitive views of emotion in both behaviourist psychology and in Freudian psychoanalysis (see Behaviourism, methodological and scientific; Freud, S.; Psychoanalysis, post-Freudian). Philosophers such as Anthony Kenny, Robert Solomon, Robert Gordon, William Lyons, Ronald de Sousa and Michael Stocker have by now demonstrated the poverty of such accounts and our need for some type of cognitive view (see Emotions,nature of §2). (Kenny also in the process offered cogent criticisms of Hume's elusive and influential account.)

During this period, cognitive psychology was itself evolving. By now, psychologists no longer expect to be able to give purely behavioural accounts of emotion in terms of stimulus and response, and most of the dominant accounts hold that emotions are a form of intelligent interpretation in which an animal takes in news of how things are in the world with respect to its most important goals and projects. Richard Lazarus (1991) has argued that emotion's evolutionary contribution is best explained this way: emotions give animals information that is essential to survival. Psychologists generally agree that we have reason to credit many animals at least with the capacity for complex appraisals suited to this account of emotion. Their work has enriched the philosophical debate.

At the same time, anthropologists have produced fascinating accounts of the role played by social norms in shaping the emotion-categories of different societies. These accounts raise questions about the extent to which an emotional repertoire is malleable; at least with respect to specific sub-types and internal demarcations within categories, there appears to be considerable cross-cultural variation in emotion-types, and also, presumably, at least some variation in emotional experience (see Moral sentiments §3; Morality and ethics §4).

This returns us to the moral problem with which the Stoics grapple: for if we see that emotions are learned with the learning of social norms, and we are convinced that our society is not perfect, then it might be unwise to trust the emotions too much as guides to conduct. One society described by anthropologist Jean Briggs (1971), the Utku Eskimos, actually embodies a relatively successful Stoic programme for the elimination of anger, thus prompting us to ask how we should think about our own goals and moral projects.

7 Feminist accounts of morality and emotion

Women have frequently been devalued on the grounds of being emotional and making decisions by consulting emotion. This has led many feminist thinkers to defend the contribution that emotions might play in moral reasoning, arguing that it is the (male) denigration of emotion that is mistaken. Philosophers such as Annette Baier, Lawrence Blum, Sara Ruddick, Virginia Held and Nel Noddings have defended a normative ethical view in which care for others plays a central role, and have seen this as a way of promoting feminist goals (see Feminist ethics).

On the other hand, feminists who consider the social origins of the appraisals involved in emotion have reasons for doubt. If women have a great propensity to care for others, is this always a good thing? Is it not the case that men have standardly urged women to see themselves as care-givers, rather than as sources of worth and agency in their own right? J.S. Mill (1869) argued that even women's desire to please men has a social origin and is a legacy of women's subordination. This line of argument has been continued recently in the work of Catharine MacKinnon (1989), who argues that women's emotions and desires are in significant ways created by inequality and injustice, and that we should therefore be highly sceptical of the claim that women's instincts of care are always trustworthy and morally valuable.

It is not necessary to choose between these extremes. We can hold that many emotions are valuable parts of the moral life without giving implicit trust to any that have been shaped in imperfect and unjust social conditions -

judging, with Aristotle and Adam Smith, that emotions can be good guides as elements in a life organized and examined by critical reflection.

Morality and ethics

Morality is a distinct sphere within the domain of normative thinking about action and feeling; the whole domain, however, is the subject of ethics.

How should the moral sphere be characterized? The three most influential suggestions are that morality should be characterized by its function, *by the* supremacy *of the moral, or by the distinctive moral* sentiments. *It is plausible that moral codes have a social function, such as that of maintaining beneficial cooperation; but it does not seem an a priori truth. In contrast, it may be true a priori that moral obligations are supreme - accepting an obligation as moral is accepting that it should be carried out whatever else may be said against doing so. But even if this is a priori, it does not provide a criterion for demarcating the moral. A better characterization takes an obligation to be moral if and only if certain sentiments, those invoked in blame, are justified towards an agent who fails to comply with it.*

This provides a criterion for demarcating the moral, but only if the sentiments can be identified. The sentiment at the core of blame is sometimes held to be a species of anger - indignation, for example. However it seems that one may feel the sentiment involved in guilt or blame without feeling indignation. A view deriving from Hegel's conception of wrongdoing may be more accurate. Whereas indignation disposes to aggressive restorative action, the sentiment of blame itself disposes to withdrawal of recognition, expulsion from the community. Punishment can then be seen, with Hegel, as a route whereby recognition is restored.

Criticisms of morality are broadly of two kinds, though they often overlap: that moral valuation rests on incoherent presuppositions, and that morality is a dysfunctional system. The leading source of the first kind of criticism (and one source of the second) is Nietzsche; in contemporary philosophy related ideas are developed by Bernard Williams. One of Williams' criticisms centres on something which does indeed seem to be presupposed by moral valuation, at any rate in modern moral thought: that moral obligations exist independently of one's desires and projects yet of themselves give one a reason to act. Other doubts about the coherence of the moral focus on a conception which, again, may be distinctively modern - being associated particularly with some forms of Protestant Christianity and with Kant; the conception takes it that all are equally autonomous and that the only true worth is moral worth. Criticisms of this conception occur (in different ways) in Nietzsche's treatment of modern morality and in Hegel's treatment of what he calls Moralität.

The idea that morality is dysfunctional, that blame and guilt deny life or impose pain without securing compensating gains, has considerable influence in contemporary culture (as does the idea that they are compromised by the interests of those who can shape them). Such criticism must come from a conception of ethical value, and assume that there is an alternative to morality. Unless one believes in the possibility of a communal life unmediated by any disciplinary forces at all, the assumption being made must be that there could be a discipline which was better, ethically speaking, than the discipline of guilt and blame.

1 Morality, practical deliberation and ethics

Morality is but a part of the whole domain of normative thinking about action and feeling. Many questions about what one should do or what kind of activity or character one should admire are not ordinarily held to be moral questions. Furthermore, it may be asked whether one should do what one has a moral obligation to do, or why one should do it. The question is not empty: those who ask it are not asking whether or why they should do what they should do, or have a moral obligation to do what they have a moral obligation to do. They are deploying two distinct concepts.

It is possible to go further and be sceptical about the very tenability of the notion of moral obligation, without denying that there are reasons for acting (see Moral scepticism). In a well-known passage, Nietzsche denies that any moral judgment is true. He denies morality, he says, as he denies alchemy. But he adds:

> It goes without saying that I do not deny - unless I am a fool - that many actions called immoral ought to be avoided and resisted, or that many called moral ought to be done and encouraged - but I think that the one should be encouraged and the other avoided *for other reasons than hitherto*. We have *to learn to think differently* - in order at last, perhaps very late on, to attain even more: *to feel differently*.

(1881: §103; original emphasis) (see Nietzsche, F. §§8-9)

We may use the term ‘ethics’ broadly to cover the normative theory of conduct, of what reasons there are for doing this rather than that. Through its concern with reasons for action, ethics will also be concerned with ideas about ends and character-ideals in so far as these bear on action (see Ideals). And by that route it also becomes concerned with questions about what there is reason to feel, and how reasons to feel connect with reasons to act. Inevitably, then, it shades into aesthetic questions; but not all questions of value dealt with in aesthetics fall within its scope. The dominant concern of ethics is conduct, right action - right feeling comes in in so far as it bears on right action rather than as a fully general subject of study in its own right. In this broad sense Nietzsche’s repudiation of morality and insistence that we have to learn ‘to feel differently’ remains an ethical teaching.

2 Characterizing the ‘moral’

How then is morality to be characterized? A number of suggestions have been put forward.

(1) By its *function*. Morality is that set of convictions whose function is to promote human flourishing, to enable us to live together on terms of mutually beneficial cooperation - or whatever one’s doctrine as to its function may be. (2) By its *supremacy* in relation to other deliberative conclusions. Morality is a subsystem of deliberation about what one ought to do, whose conclusions in principle override all others. To take an obligation as a moral obligation is to take it that one should fulfil it whatever else can be said against doing so. (3) By the distinctive *sentiment* which is involved in moral valuations (see Moral sentiments). On this view, a precept is moral if particular sentiments are appropriate towards those who do not comply with it - the sentiments involved in guilt and blame (see Praise and blame; Rectification and remainders §4).

According to (1), then, the morality of a society will consist in those of its generally acknowledged rules or convictions which can be characterized as functioning in it to produce a certain outcome. If this is taken as a definition, ‘morality’ is a functional term, like ‘tuner’. A tuner in a sound system is by definition the device in the system whose function is to enable a user to select and receive radio signals. It is not obvious, however, that there is any function which morality by definition has. Certainly it is plausible that the existence of commonly acknowledged moral convictions has the effect of facilitating, for example, beneficial cooperation. But to say that that is their function, as against their consequence, is to say something stronger: roughly, that that is what they are there for. This is a substantial thesis. It may be true, for instance, in virtue of natural selection, or God’s design (Evolution and ethics; Religion and morality §3). Even if moral convictions do have a particular function, though, it is still not obvious that that is what it is, by definition, for them to be *moral* convictions.

(2) holds that the criterion of morality is the supremacy of moral obligations. In a positive sense the morality of a person or society is that which they take to be supreme; in a normative sense morality is that which is supreme. In the normative sense, then, accepting that an obligation to do X is a moral obligation is accepting that the obligation is of such a kind that one should do X whatever else can be said against doing X.

But what kind of obligation is that? In one sense any deliberative conclusion about what I should do, all things considered, is supreme: if my conclusion is correct then I should do that thing, whatever it is, despite everything which can in fact be said against it. However the idea of supremacy is that the total set of considerations, moral and nonmoral, cannot outweigh the moral ones alone. This may be true, and indeed true a priori. But it cannot serve as a definition because it already presupposes a distinction between moral reasons and reasons other than moral ones.

Consider (3). Hume said:

> When you pronounce any action or character to be vicious, you mean nothing, but that from the constitution of your nature you have a feeling or sentiment of blame from the contemplation of it.
>
> (1739-40: 469)

He appears to define moral censure in terms of the feeling or sentiment of blame - but too simply. Suppose I pronounce something to be vicious without having any feeling or sentiment of blame towards it. It does not follow that my pronouncement is false. The question of its viciousness turns rather on whether it is appropriate or reasonable to blame it. So a better analysis would make the normative element explicit: when you pronounce any

action to be vicious you are claiming that the feeling or sentiment of blame is an appropriate response to its agent. This explicitly normative line was taken by J.S. Mill (1861); he implied that believing oneself the object of justified blame is already a form of punishment. This 'idea of penal sanction' enters into the notion of moral wrongness: an action is morally wrong if it is appropriate to respond to it with the penal emotions involved in blame (see Mill, J.S. §11).

3 Blame

Blame is an act which stands to a specific feeling, the blame-feeling or sentiment of disapproval, as the act of apology stands to feeling sorry, the sentiment of regret. In each case the action is a judgment that a certain feeling is appropriate towards an action. This is a narrow notion of blame, blame as censure. It is not the wider notion in which we can blame the cheap pen for the ink blot or the weather for the traffic delays. For we are not then saying that a particular penal sentiment is appropriate towards them, but only that they were the relevant cause of a bad outcome (see Praise and blame §1). Note also that since blame is an action, not a feeling, there may be situations in which it is unreasonable to blame explicitly, or blame at all, even though it is reasonable to feel the sentiment which is invoked in blame. If someone is in an emotionally distressed state it may be wrong to burden them with blame even if they are indeed blameworthy. And it might be expedient to put aside guilt feelings, refrain from self-blame, when time is short and there are things to be done, even though the feeling is reasonable. So defining the morally wrong as the blameworthy - understood as that towards which it is reasonable to have the blame-feeling - leaves open the possibility that one should not blame an action even though it is morally wrong.

If the morally wrong is characterized as the blameworthy it becomes possible to characterize the other moral concepts by reference to the sentiment of blame. The morally right is that which it is morally wrong not to do. 'X is morally obligatory' will hold just if non-performance of X is blameworthy. We admire people for going beyond the call of duty even though we do not blame them for not doing so: admiration of such actions is moral admiration if we admire them for the reasons that impelled them and those reasons are moral reasons (see Supererogation). And we can say that they are moral reasons - as against, say, prudential or aesthetic reasons - when their absence from a person's mind beyond a certain point becomes blameworthy. The virtues involve sensitivity to various types of reason for acting which we recognize as moral reasons; they are also traits of character which we could be blamed for not attempting to attain or lose, when it is possible for us to do something to attain or lose them (see Virtues and vices §§2-3). This sets them apart from admirable qualities in general.

The last point is controversial. Hume (1748, 1751) treated the distinction between virtues and talents, vices and defects, as 'merely verbal', and understood blame in a correspondingly wide sense, as referring to any disvaluing emotion. He took himself in this respect to be following the ancients. Aristotle, for example, argued that we disapprove of those who become ugly through 'want of exercise and care' (*Nicomachean Ethics* 1114a23-25). (He is translated as saying that we 'blame' or 'censure' them, but these words may be too narrow for the kind of disapproval, thinking less of, that he has in mind.) But he added that we do not disapprove of those who are naturally ugly - maintaining a link between disapproval and the voluntary even if he does not distinguish moral defects from disapprovable defects in general (see Aristotle §20). Now, however, we do make the distinction and it plays a role in our feelings. We would blame a person who is wantonly ugly only in contexts which generated an obligation to look after one's looks (they accepted a job as a model and bankrupted the company). Otherwise their ugliness, whether it be natural or wanton, may provoke derision or disesteem - and disapproval if it is wanton, though it still remains their business. Thus we make a three-way distinction between moral blame, more general forms of disapproval which link with the voluntary, and disvaluing emotion as such. If Aristotle seems to conflate the first two elements in the distinction, Hume seems to conflate all three.

On the other hand Mill's notion that moral disapproval is penal picks out the relevant difference. But even if we accept that there is a distinctively penal sentiment of blame it does not follow that the morally wrong can be defined in terms of it as that towards which it is a justified response. This could not, in the first place, be a definition if it proposed that the morally wrong is that which there is a moral obligation to blame. We have distinguished, however, between the act of blame and the sentiment of blame itself; to judge that the sentiment is justified is to make a judgment about what one ought to feel in the sense of what feeling is reasonable. That need not be, arguably cannot be, a moral 'ought'.

A more serious objection arises from the intentional content of the blame-feeling. Is not the blame-feeling directed

properly only at that which is believed to be morally wrong? This circularity is harder to set aside; it may force the conclusion that 'morally' in 'morally wrong' is a semantically primitive modifier (see Skorupski 1993). But even so the thesis that an action is morally wrong if and only if the sentiment of blame towards its agent is justified (or some refinement of that thesis) may be a conceptual truth which supplies a criterion for demarcating the moral system of evaluations in a society from others, by reference to the distinctive sentiment involved in guilt and blame - so long as we can get some independent grip on that sentiment.

Characterizing morality in this way is consistent with holding that it has a function. Our spontaneous responses as to what is reasonably blamed serve to maintain beneficial social cooperation; it is not implausible that they persist in their character and content because they do that. What of the supremacy of morality? Is the claim that moral obligations are overriding consistent with characterizing the moral in terms of sentiments of blame? Suppose it would be blameworthy not do X. Does it follow that one should do X, whatever can be said against doing it? At least this much seems true: if there is no reason why a person should not do X - where 'reason' is being used in the general deliberative way - then there is no reason to blame that person for doing X. This is a point about the intentional content of the blame sentiment, like the point that if something is in no way dangerous there is no reason to fear it. If it is correct, and if an action is morally wrong just if it is reasonable to blame a person who does it, then it follows from the fact that it is morally wrong that there is reason not to do it, without need of any extra premise. We might call this the thesis that morality is constraining. To say that morality is supreme is stronger. It requires something like this: if doing X is, all things considered, optimal (there is nothing there is more reason to do) then there is no reason to blame a person for doing X. If that is intrinsic to the intentional content of the blame sentiment, then so is the supremacy of morality.

4 Do all societies have morality?

All sustainable societies have spontaneous disciplinary systems maintaining solidarity and prohibition - in the sense that they flow from spontaneously shared favourable and hostile attitudes to actions and are not codified systems of law enforced by instituted penalties. Artificial disciplines psychologically presuppose them and could not sustainably replace them, not just because (outside utopia) the enforcement costs would be too great.

But need these spontaneous disciplines be based on the emotions involved in guilt and blame? Here questions on the borders of philosophy and anthropology arise. Among them are: How do guilt and blame relate to or depend on religious emotions of transgression and expiation or redemption, or to emotions mobilized by the ideas of purity and pollution? And how are they related to shame and disdain? A distinction has been proposed between shame cultures and guilt cultures; spontaneous discipline is realized in the former through the experience of shame rather than of guilt (Benedict 1947). E.R. Dodds (1951) suggested that the development from Homeric to classical Greece was a development from shame to guilt culture; the Christian West is often thought of as *par excellence* a guilt culture (see Moral sentiments §3).

In attempting to pin down a sentiment one looks to its intentional content and the action to which it disposes. Some have suggested that the core of blame is a species of anger - indignation or resentment. Resentment, however, is specifically occasioned by what is taken as injury to oneself. Indignation, it is true, is more general: it is occasioned by what is taken to be wrongdoing whether or not it involves injury to oneself. Yet it seems mistaken to make it the emotional core of blame, even though wrongdoing is its object. Rather, indignation is what people of spirit feel on witnessing a religious or moral violation. It impels them to right the wrong done, aggressing if necessary against the violator. The blame-feeling as such does not dispose to aggressive restorative action: it resembles, in extreme cases, a kind of horror akin to the reaction to pollution and disposes to withdrawal of recognition, casting out of the community (see Recognition). It further disposes to punishment; but punishment is not the expression of anger. When it is not a simple deterrent discipline it is an atonement - a regaining of recognition. Or rather, punishment as such is never just deterrence. The concept is not applicable to the entirely wild, though it can apply in some degree to animals which are incorporated into the social order. The blameworthy but unpunished agent is in a liminal state between community and wilderness. Hegel held punishment to be the right of the wrongdoer; his view is understandable when punishment is seen as the mechanism for regaining recognition. Expulsion is the first moment of blame, redemption and return the second and third. The punishment must be accepted: guilt - self-blame - is a withdrawal of recognition from oneself and a movement to redeeming self-punishment.

This human pattern which lies at the core of blame can plausibly be held to exist in all cultures. But that does not mean that institutional and ideological structures which mobilize and channel it do so in the same way or degree. For example many societies connect transgression to impurity or pollution, and associate with them rituals of cleansing such as the scapegoat carrying its burden of evil into the wilderness (see Atonement). (The impure can have unexpected connections with the sacred: the impure transgresses law, the sacred is above it.) Christianity's heaven and hell take integration into the community or expulsion from it to their furthest limit; this life becomes a liminal phase preceding final integration or expulsion. But we should not infer too easily that the very notions of wrongdoing and punishment depend on such religious or magical extensions. They remain the root notion of criminal as against civil law, for example, even when law is shorn of magic and religion.

How then do guilt and blame contrast with shame and disdain? Central to those latter feelings is the notion of personal standing, status or rank. The behaviour to which disdain disposes is not exclusion from the community but demotion within it, not withdrawal of recognition as such but loss of status. Shame, disdain directed towards oneself, is the experience of loss of standing in one's own eyes. With loss of standing there is no analogue to the recognized antidote, so to speak, provided for exclusion by atonement. Presumably that is because standing requires qualities that may be non-voluntary whereas membership only requires compliance (see Honour). Blame relates to the quality of the will, something redeemable of whose redemption one can give a sign; whereas disdain need not. A shameful defect is not necessarily, or even typically, a defect of will and it may not be possible to remedy it by effort.

The responses of exclusion and demotion are elemental, but develop and shade into each other in many ways. A contrast between 'blame cultures' and 'shame cultures' may be too simple to capture the diversity and continuity among cultures that is actually found. Yet it is plausible that modern Western culture stands out by the marked reliance it places on the discipline of guilt and blame and the way it isolates or 'purifies' that discipline, shearing it of any magico-religious setting, distinguishing it from customary law, and disentangling it from systems of shame and disdain, which it radically downgrades (the most recent step in this process has been the removal of shame from the sexual domain). Theologically, this tendency was led by Protestant Christianity; philosophically, it is epitomized in the abstract, though not the practical, ethics of Kant. One can seek to explain it in various ways: by the internal dynamics of the West's Judaeo-Christian legacy, or as part of the transition from aristocratic values to modern bourgeois notions of individual responsibility, or simply by the general modern tendency to differentiate social functions (see Responsibility). These questions belong to the humanities as a whole. But there is also a question of ethical assessment which must be of special interest to moral philosophy. Granting that the modern West is singular in the degree to which, and the way in which, it isolates and relies on guilt and blame, is this reliance wise? Or does it throw up illusions and downgrade valuable ideals? Does morality as we have come to understand it - 'modern morality' - play an indefensible role in our ethical thought? It was Nietzsche's achievement to put these questions firmly on the agenda. In recent moral philosophy they have been pursued by Bernard Williams (1985; 1993).

5 Criticisms of morality

Criticisms of morality - or of 'modern morality' - fall into two kinds, claiming respectively that it is incoherent and that it is dysfunctional.

The object of the blame-feeling seems to be, as one may call it, transgression. Transgression is avoidable wrongdoing. It is recognizable as such by a responsible agent; responsibility is the capacity to respond to it as 'constraining' in the sense explained in §2 - to acknowledge that there is reason to avoid it as such. Moreover transgressive wrongness is a wrongness independent of the agent's desires and projects. Bernard Williams criticizes this idea of wrongdoing on the ground that there are no 'external reasons' - nothing which one has reason to avoid as such, irrespective of one's desires or projects. If transgression is indeed the intentional object of the blame-feeling, his criticism undermines the coherence of blame: it would follow that nothing is blameworthy, in the way that if nothing is dangerous it follows there is nothing to fear. Williams (1985; 1995), however, holds this notion of wrongdoing, and the corresponding notion of responsibility, to be a fiction peculiar to what he calls 'the morality system' - in present terms, modern morality (see Williams, B.A.O. §§2-3).

Whether there are 'external reasons' is a controversial issue in epistemology and the philosophy of mind (see Moral motivation). Williams' rejection of external reasons stems from a neo-Humean view of those issues which

has been widely influential but is also widely rejected. However there is a distinct criticism, of modern morality at least, also sketched by Williams. Modern morality seems to hold that those who are bound by the moral law at all are bound by it equally. Is this inherent in the blame-feeling as such? Certainly the blame-feeling presupposes no doctrine of degrees of rank, or of ideals of life underpinning such degrees - disdain in contrast works with a notion of what can be expected from the superior and the inferior. But modern morality seems markedly to strengthen this feature of the blame-feeling. Kant (1785) stressed that the moral law must be accessible to any autonomous being and it is part of his metaphysics of the person that everyone has an equal potential for rational autonomy (see Autonomy, ethical). More generally, the problem of 'free will' is typically presented in modern moral philosophy as an all or nothing affair: either all lack free will and thus responsibility (because of the truth of determinism, for example) or all are equally free; either way there are no degrees of moral agency (see Free will). A connected and very powerful modern thought is that no system of valuation has the existential finality of the moral. Its extreme formulation is Kant's thesis that the only real human worth is moral worth; it fits onto the thesis that all are equally capable of acknowledging and acting on the moral law. Taken together the two theses imply that differences of human worth stem exclusively from what is equally within all human agents' control. One may call the idea that this must be so the egalitarianism of pure desert, or of pure autonomy.

The right response to it may be that moral agency does come in degrees and that there are admirable or contemptible forms of agency other than the moral. This may be incompatible with the egalitarianism of pure autonomy but is it incompatible with morality as such? Ordinary moral thought is quite willing to allow that there can be diminished responsibility and that it implies diminished blame. It also allows that natural virtues may be differentially distributed and it does not extirpate systems of valuation other than the moral. Perhaps the egalitarianism of pure autonomy or desert arises from the profoundly Christian, or more narrowly, Protestant character of modern ethical thought and not from moral valuation, grounded in the sentiment of blame, as such.

These lines of response take account of Nietzsche's criticism of Christianity and modern morality (see §1) but seek to disentangle it from his rejection of moral valuation itself. Another influential critique, which focuses on somewhat related aspects of modern morality, is found in Hegel's *Philosophy of Right* (1821). Here too a contrast between Hellenic and modern ethical conceptions plays a vital role. Hegel divides the ethical sphere, which he thinks of as the sphere of freedom, into three aspects or phases - 'abstract right', *Moralität* and *Sittlichkeit* (see Hegel, G.W.F. §8). Abstract right treats of the external, juridical regulation of persons conceived of as property owners and the rights implied thereby. The latter two terms are usually translated as 'morality' and 'ethics' or 'ethical life', but in the present context those translations are misleading, for both terms denote aspects or kinds of morality. *Moralität* develops the subjective side of moral agency. Hegel takes as its characteristic form the Kantian notion of a self-legislating subject evolving, entirely from its own reflection, the content of the moral law. He sees this, in particular its idea that true moral agency arises from rational insight into universal law, as a moment in the development of modern freedom from primitive *Sittlichkeit*, or communal moral order. But he also holds that it is doomed to emptiness by its own purism. Taken as rejection of the very possibility of abstract ethical theory, as it sometimes is, Hegel's criticism would be vitiated by its excessive focus on the specifically Kantian treatment of the issue. But if it is seen as a criticism of the ahistorical and asocial distortions which modern morality's egalitarianism imposes it is on target. It is a critique of the one-sided subjectivity or individualism of certain modern conceptions of moral valuation - but Hegel also thinks that this one-sidedness is bound to be overcome. In modern *Sittlichkeit*, the objective ethical life to which Hegel thinks modernity eventually tends, moral valuation is relocated in institutions whose rationality enables one to achieve freedom by taking up a social role.

Rejecting some of the distinctive components in the ideology of modern morality, then, is not necessarily rejecting morality as such. But it may still be asked whether it is a good thing to entrench the emotions of guilt and blame into a social discipline. The question must come from some conception of ethical value, and it must assume that there is an alternative. To think morality is dysfunctional one must have an ethical end in mind which is not itself moral. For example, a utilitarian might claim that the blame-sentiment should be downgraded as dysfunctional, perhaps after some level of social development has been reached (see Utilitarianism). Blame and guilt are after all hostile feelings which cause pain. Yet is there any conception of ethical value which does not make the idea that we would be better off without the social authority those feelings presently carry utopian? Can human beings reach a level of rationality or goodness at which the need for any discipline, spontaneous or artificial, drops away? If not, the choice lies between spontaneous systems and costly and repressive artificial ones, and then within the

spontaneous, between the system of guilt and blame and other systems such as that of shame and disdain. A society which shifted emphasis towards the latter would also have to shift - how far is hard to tell - from modern individualism and egalitarian respect.

Morality and identity

Philosophers have drawn connections between morality and identity in two ways. First, some have argued that metaphysical theories about personal identity - theories about what makes one the same person over time - have important consequences for what ought to matter to a rational agent. Second, others have argued that understanding the concrete identities of persons - the social contexts and personal commitments that give life substance and meaning - is essential if moral philosophy is to address real human concerns.

How are metaphysical questions about personal identity supposed to bear on morality? The thought is that what unifies a series of experiences into a single life illuminates what we are, and what we are helps determine how we ought to live. More broadly, it is natural to seek coherence in our metaphysical and our moral views about persons. This pursuit of a comprehensive account has its dangers; perhaps we will tailor a metaphysical view to fit our moral prejudices, or distort moral philosophy and judgment to fit a false metaphysics. But the pursuit has its attractions too; perhaps we will come to understand what we are, and how we ought to live, in a single package.

Philosophers who attend to concrete rather than metaphysical identity characterize persons as committed by social and historical circumstances to a particular range and ordering of values, and as committed by proximity and affection to a particular circle of other persons. These concrete and individual characteristics at least constrain what morality can reasonably demand. But this interpretation suggests that morality stands back from the rich texture of each life, and moderates its demands to accommodate that life. Some philosophers think of morality instead as part of the texture, as intimately connected to, rather than constrained by, concrete identity.

1 Some historical background about personal identity

Does anything about a person survive bodily death? This is a natural way for metaphysical questions about identity to acquire practical and moral urgency (see Personal identity). For example, Plato argued for the existence of an immortal soul, and used this metaphysical view to buttress his moral claims (see Plato §13). Thus, it is always wrong to harm others because doing so also harms your soul, the most enduring and valuable part of yourself. Theologians too have an abiding interest in such issues. For whether persons survive in resurrected bodies or as permanently disembodied souls, they must survive in *some* form to receive God's justice, or God's mercy. The thought of such justice and mercy plays an important moral role for many religious believers (see Soul, nature and immortality of the).

In his paper, 'Of Identity and Diversity' (1694), John Locke focuses not on what might survive bodily death, but on what accounts for identity over time during our earthly lives (see Locke, J. §9). Locke invites us to imagine these possibilities: two sets of character traits and memories (or, for brevity's sake, two psychologies) alternate in possession of a single body; a single psychology is transferred from one body to another; a single soul is associated with two different psychologies; a single psychology has 'underlying' it not a single soul, but rather a rapid succession of souls. Locke argues that our best responses to these imagined cases indicate that neither sameness of body nor sameness of soul is necessary or sufficient for identity. Instead, the right kind of psychological continuity determines personal identity over time.

Locke's positive theory of personal identity has been dubbed the memory theory: at time t_2, I am identical with a person at some earlier time t_1 if and only if I can remember the t_1 experiences *as my own*. This theory gives rise to numerous problems; Locke himself broaches some of them. For instance, Locke admits that, were he to lose irretrievably the memories of certain experiences, he would no longer be the same person that had those experiences. But he tries to soften this odd-sounding claim. He says that he would be the same biological being ('man') in spite of his forgetting; but he would not be the same *person*, because a person is an amalgam of the actions for which that person can take responsibility, and one cannot take responsibility for what one cannot remember. So Locke's sense of the moral role of the concept of the person shapes his metaphysical account of personal identity.

Such manoeuvres did little, however, to forestall criticism of the memory theory. Some criticisms focused simply on identity: Thomas Reid, for instance, elaborated variations on the theme that forgetfulness does not destroy identity (see Reid, T. §7). But some criticisms were moral: Joseph Butler argued that the memory theory provides

such a loose sort of identity that it renders our ordinary self-concern mysterious (see Butler, J. §6). The deeper aim of such critics was to restore the soul to its rightful identity-producing role. But they failed to counter Locke's arguments against the soul's having such a role.

David Hume, in his *Treatise of Human Nature* (1739/40), extended Locke's criticisms of the enduring-soul theory of personal identity by arguing that the concept of the soul has no empirical content. He also revised Locke's positive account of identity by supplementing memory with causation. It is appropriate to speak of a previous experience as my experience, Hume says, even if I cannot remember it, if it played some suitable role in causing other experiences of mine. Hume further claims that all experiences or perceptions are, strictly speaking, 'loose and separate', so that the idea of personal identity over time is a fiction, even if an indispensable fiction (see Mind, budle theory of). But Hume draws no moral conclusions from this extreme or sceptical view. Instead he draws moral conclusions from his attack on the soul, supporting his opposition to religious values ('monkish virtues') by denying the favourite religious account of personal identity.

2 Parfit's metaphysical and moral revisionism

In *Reasons and Persons* (1984), Derek Parfit revives and extends Lockean and Humean themes. Parfit argues that ordinary beliefs about personal identity are mistaken, and that correct beliefs about identity might engender altruism and support consequentialism (which says that an action is right if it promotes the best outcome overall, impersonally considered) (see Consequentialism; Egoism and altruism).

Parfit first describes ordinary belief. We do not believe that the changing surface facts about us account for personal identity over time. Instead, some unchanging 'further fact' constitutes personal identity. When this further fact has received any explication, it has been understood as the Christian soul or the Cartesian ego.

However, Parfit says, there is no good reason to believe in any such further fact. To bear out this and other claims, Parfit produces thought experiments along Lockean lines, but fleshed out with science-fiction details; for instance, he imagines cases of teletransportation and of brain fission. The former procedure involves destroying a body at one place and simultaneously creating a precisely similar new body, realizing a precisely similar psychology, at another place; the latter procedure involves splitting the brain in two and transplanting each half into a new body. Examining our best responses to such cases shows us that we ought to be *reductionists* about personal identity, and that the right kind of reductionism is *psychological* (see Personal identity §3). Personal identity over time is constituted by the holding of certain psychological relations (which Parfit labels 'Relation R'), whether the physical cause of these relations is the stuff of science fiction, or is familiar and normal. (The normal cause of Relation R is the spatiotemporal continuity of the body, including the brain, that realizes the related psychologies). There is, though, this proviso: however extensive the psychological relations that hold between A at t_1 and B at t_2, A and B are not the same person if there exists at t_2 another person, C, whose psychological relations to A are equally extensive. In Parfit's terminology, identity requires that there be *no branching*.

Parfit claims that, from his general account of the metaphysics of identity, it follows that identity (1) is not all-or-nothing and (2) is not 'what matters' (what is most valuable to a rational agent). These conclusions challenge ordinary practical reasoning, which gives pride of place to the determinate and meaningful self.

(1) Identity (hence survival) is a matter of degree, rather than all-or-nothing, for psychological relations that are themselves a matter of degree constitute identity. We can imagine cases where many identity-producing psychological relations hold, but many do not, so that we are *unsure* whether these are cases of identity and survival; our uncertainty shows that in such borderline cases there is no fact of the matter about whether the later person is identical to the earlier person. But even in mundane cases, the unity of a person's past, present, and future 'selves' is a matter of degree, constituted by Relation R. And Relation R holds not just *within* persons, but also *across* persons; for two people can share many values and projects and character traits. So the same relation that imperfectly unifies the self also connects us with other people.

(2) In branching cases, the kind of psychological relation that obtains in unproblematic instances of identity obtains twice. But this very surplus rules out identity-claims; for we should not say that two numerically distinct persons are *both* identical to some earlier person, and we have no grounds for preferring one identity-candidate to the other. Now Parfit believes that few people would say that a branching case is as bad as ordinary death; and

most people would say that such a case is about as good as ordinary survival. (The imagined future contains two agents who share your values, and will pursue your projects as you would have.) Thus branching cases contain what matters in ordinary survival, without containing identity. Parfit concludes that, even in ordinary cases, what matters in survival is not identity, but the obtaining of the right psychological relation with some future person.

What, then, is Parfit’s desired practical and moral upshot? He hopes that the reductionist will have more reason to be *impartial* and *impersonal* than the non-reductionist does (see Impartiality). For reductionism lessens the gap between persons. It shows that my relation to other people is more like my relation to my own past and future than non-reductionist common sense allows. So reductionism undermines the belief that it is most rational for me to pursue my own long-term self-interest; and believing reductionism might cause me to promote my values and projects (part of the content of Relation R) without special regard for the particular people involved. Thus reductionism might move us towards greater *altruism*; and, because this altruism focuses not on other enduring individuals but on impersonally promoting certain values and projects, reductionism might move us closer to *consequentialism*.

However, Parfit qualifies these conclusions, in two ways. First, he admits that a rational person could believe that only a further fact could be what matters, so that reductionism would show that nothing matters. Parfit believes this ‘extreme view’ is rationally indefeasible, but also not rationally compelling. That is, Parfit believes his own optimistic view about what matters in the absence of a ‘further fact’ is as rational as the extreme view is. Second, Parfit hopes not that people will become selfless, only that they will become somewhat less self-interested, when they learn the reductionist truth about personal identity. He suggests that there are evolutionary reasons for thinking in terms of identity, and for acting in self-interested ways (see Evolution and ethics §2). But, where hope for psychological revolution might be naïve, hope for psychological reform might be well-grounded. Parfit hopes for reform, in the direction of consequentialism, once people become reductionists about personal identity.

3 Criticisms of Parfit

We now consider four main criticisms of Parfit.

(1) The most straightforward and ambitious criticism says that personal identity *does* consist in the holding of some ‘further fact’ (the existence of an unchanging soul). Making out this criticism involves showing that the scientific picture of human beings is irremediably incomplete, or at least that Parfit offers no good reason for thinking otherwise. Assessing this ambitious criticism is beyond this entry’s scope; but it is worth noting that the criticism attacks Parfit at his strong point, and where he can find many allies.

(2) A subtler criticism of Parfit’s metaphysics agrees that some form of reductionism is correct, but disagrees with his permissive attitude towards the cause of Relation R and with his exclusively psychological reductionism. The critics (including Peter Unger (1990)) argue that Parfit underestimates the importance of the normal cause of Relation R, namely the physical continuity of a living body. The most plausible reductionism refers to both psychological relations and physical continuity. This partly-physical reductionism captures our deepest notions about what makes for the same person over time in our usual circumstances; the appeal of disembodied Cartesian egos or of Parfitian teletransported psychologies is shallow, compared to the appeal of an embodied this-worldly self. Partly-physical reductionism also does *not* commit us to substantially revising our deepest values. Instead, it helps explain why we value whole persons and maintain clear distinctions between persons, rather than valuing isolated psychological characteristics and blurring the distinctions between persons.

(3) Parfit believes that it is possible and desirable to become less committed to particular persons (oneself included) and more committed to general features of people (character traits, patterns of concern). But perhaps it is a practical necessity that we conceive and order our commitments in terms of whole and enduring persons - enduring, that is, at least over the course of a lifetime. Or perhaps, though we *might* come to think of the human world as a collection of psychological characteristics variously related, this new way of thinking would impoverish our lives. For instance, it might might make it hard for us to conceive of love or friendship.

(4) Parfit argues that ordinary normative practices are founded on false metaphysics, and that coming to believe the true metaphysics gives us opportunity and incentive to revise our practices. But perhaps our practices are founded not on any metaphysical view about persons, but on our circumstances and needs. Perhaps ordinary non-reductionist metaphysics is just window-dressing.

To each of these last three criticisms, Parfit's best response might be a partial accommodation. He has been willing to entertain the possibility that the best reductionist account of personal identity refers to the normal cause of Relation R. He admits that there are limits to our ability to excise identity from practical reasoning, and that even a partial excision must be judged by its consequences. Finally, it would indeed be unreasonable to claim that *all* our ordinary practices are *entirely* shaped by false metaphysical views; but it is possible, perhaps likely, that *some* practices are *partly* shaped in this way. (But which practices depend on false metaphysics? To what extent? Can we revise the practices to fit the true metaphysics? Is this revision morally desirable?)

4 Concrete identity

Advocates of 'concrete identity', the second broad approach to connecting issues of morality and identity, side with Parfit's critics. Parfit's view is, according to concrete identity theorists, one manifestation of a widespread mistaken approach to ethics - an approach that abstracts away from the richness of actual psychology and social and historical context, thus losing sight of real human lives. Kantians appeal to a general and formal feature of persons, their rational agency, in constructing moral theories and testing moral injunctions (see Kantian ethics). Consequentialists see persons simply as causes of good and bad consequences, or the locations where those consequences are embodied. Such artificially restricted views of the person distort one's view of morality, the concrete-identity theorists argue; to see morality clearly, we must see people whole.

Starting from this complaint about abstraction, philosophers have pursued two paths: the first psychological, the second social and historical. Bernard Williams has put the psychological case forcefully, arguing that abstract moral theories miss or dismiss important moral phenomena, and fundamental facts about human motivation (see Williams, B.A.O. §2). Effective reasons for action are deeply personal; how can the stripped-down agents of Kantianism and consequentialism have reasons to act at all? It is absurd to require that agents abandon the commitments that give their lives shape and meaning, in order, for example, to produce the best consequences overall. Close personal attachments have independent moral value; it is impertinent, perhaps monstrous, to demand that we justify our special attachments in light of abstract moral principles (see Friendship; Love §1). In short, moral insight into a person, and effective moral appeals to that person, had better be based on actual features of *that* person's rich psychology, rather than on abstract general features of the person or of moral agency.

Charles Taylor (1989) makes the case for a social and historical approach to concrete identity (see Taylor, C. §§4-5). Taylor does furnish a general theory of sorts about identity: each person shapes an identity through self-interpretative activity, activity that employs the interconnected resources of community, language, and a conception of the good life. This theory connects morality and identity by connecting the questions 'What do I value?' and 'Who am I?'; it also directs our attention towards social and historical particulars. So Taylor's method for investigating our moral situation is to see how the modern identity, that is the modern range of conceptions of the good life, has been shaped and enriched over a long history. The method is not to pare down the concept of identity to its essentials, but to build it up in all its complexity.

It would be folly to deny that concrete identity theorists point at important phenomena. Moral philosophers of all bents should strive at least to show that their theories are consistent with the concrete aspects of identity and of moral life; even better, moral philosophers might strive to connect the abstract and the concrete. But concrete identity theorists often aim at more than providing a salutary reminder to other moral philosophers. They suggest that abstract moral theorizing distorts our lives beyond recognition, that there is no use for the sort of abstraction that whittles people down to a few essential characteristics. In response to these ambitious criticisms, traditional moral philosophers can claim that to abstract away from psychology and culture and history, for special purposes and for the sake of clarification, is not to deny the existence or importance of the things we abstract away from. Understanding our moral lives might require that our attention move back and forth between general features of persons, and persons in their particularity.

This survey has examined two ways in which questions of identity matter to moral philosophers, and two approaches to moral philosophy. Ranged on one side are philosophers who focus on general and trans-historical aspects of being a person or a moral agent. On the other side are philosophers who focus on human beings and societies in their particularity, and who eschew abstraction (or practise a different kind of abstraction, rooted in psychological and historical rather than metaphysical facts). In spite of the apparent conflict between the abstract

and the concrete, it is unclear whether these two approaches to thinking about morality and identity are mutually exclusive, or complementary.

More, Henry (1614-87)

The English philosopher Henry More was one of the leaders of the movement known as Cambridge Platonism. Like his Cambridge colleague Ralph Cudworth, More elaborated a constructive metaphysics which, although deeply informed by the new philosophy and science of the seventeenth century, recovered what More saw as an ancient truth or 'cabbala'. The articulation of this truth was an exercise of reason, guided by innate notions or inherent, God-given cognitive propensities. More's ultimate aim as a philosopher was religious or ethical. His 'one main Design*', he explained, was 'The knowledge of God, and therein of true Happiness,*so far as *Reason* can cut her way through those darknesses and difficulties she is encumbred with in this life*' (1662: iv). Among the central themes of the ancient truth More rediscovered and defended were the existence of a God whose leading attributes are wisdom and goodness; the immateriality and immortality of the human soul (the hope of immortality being, as More explained in the Preface to his poem Psychathanasia (1642), 'the very nerves and sinews' of religion); a dualism of active spirit and passive matter that differed significantly from the dualism of Descartes, despite More's early enthusiasm for (and continuing engagement with) Cartesianism; the animation of matter by an immaterial but unthinking spirit of nature; and the existence of an infinite, substantial space, really distinct from matter, in which God is everywhere present and everywhere potentially active.*

More's appeals to experiment in defence of the spirit of nature provoked criticism from Robert Boyle. His doctrine of infinite, substantial space was (in the opinion of some historians) an important influence on Isaac Newton. Space seems, on More's portrayal, to be something divine; this troubled George Berkeley, who thought that by assigning space the 'incommunicable' or unshareable attributes of God, More in the end encouraged the atheism he worked so hard to defeat.

*More is usually represented as a rationalist in religion: '*I conceive*', he once wrote, '*Christian Religion rational throughout*' (1662: iv). It is important to distinguish, however, between More's appeal to reason as a writer defending Christianity, and his appraisal of reason's role in an ordinary Christian life. More was conscious of living in 'a Searching, Inquisitive, Rational and Philosophical Age', and he saw it as his duty to serve God by 'gaining or retaining the more Rational and Philosophical' of his contemporaries in the Christian faith (1664: 482). Rational and philosophical genius was not, however, required of every Christian: although More's accounts of faith vary somewhat from work to work, they typically call not for a rational assessment of argument and evidence, but for moral purity, and for a belief in (and devotion to) a relatively short list of 'essentials'. More sought a statement of these essentials that would reach across Protestant sectarian divides. He also defended a liberty of conscience or religion that was, he said, the natural right of every nation and every person. It was, however, a liberty that could be forfeited, and More thought it* had *been forfeited by some (atheists, for example, and at least some Catholics and Muslims) who might be found claiming its protection.*

1 Life and works

More gives an absorbing account of his early life in the general preface to his *Opera omnia* (1675-9). He was born in Grantham, England, to parents who were 'earnest Followers of *Calvin*'. He himself could never 'swallow down that hard Doctrine concerning *Fate*' because it seemed so at odds with God's justice. As a student at Eton and at Christ's College, Cambridge (where he arrived in 1631), More was possessed by an 'insatiable Desire and Thirst… after the *Knowledge* of things'. At first he took this to be a love of knowledge simply for its own sake, but when he discovered that even the most eager study of philosophy did not quench it, he determined that it was, at bottom, really a form of self-love. He resolved to extinguish or annihilate his own 'proper *will*' and seek 'full union' with the will of God, and was rewarded with the intellectual satisfaction he had earlier failed to find - a 'greater *Assurance*', he said, 'than ever I could have expected'. More became a fellow of Christ's College in 1641, and was ordained in the Church of England in the same year. His career as a writer can be divided into three broad periods, marked not by shifts in doctrine but by changes in the shape and scope of his literary projects.

In the 1640s More published a series of philosophical poems defending the Neoplatonic Christianity he embraced when he came to Cambridge - influenced not only by his study of Plato, but by Renaissance Neoplatonists such as Ficino and Pompanazzi (see Neoplatonism). These poems argue for the soul's immortality, for its pre-existence and for its consciousness after death. Memories ('the bundle of the souls duration') preserve the soul's identity

after it parts from its earthly vehicle. Memories also account, at least in part, for one soul's distinctness from others. It was in the middle of this period, around 1645, that More first read Descartes. In *Democritus platonissans* (1646: [iii]), a poem defending the infinity of worlds on new-scientific and Platonic principles, More describes Descartes as a '*sublime and subtill Mechanick*'. '*Though he seem to mince it*,' More continues, Descartes '*must hold infinitude of worlds, or…one infinite one*', because his 'indefinite' extension is simply infinite extension under another name. This is one of several criticisms More developed in letters he exchanged with Descartes in 1648-9. More's side of the correspondence is deeply respectful - almost reverential - but his disagreements with Descartes were fundamental, and as his awareness of their implications grew, More's attitude towards Descartes and Cartesianism became increasingly hostile.

In the 1650s More translated the philosophy of his poems into prose. Works published in this second period include *An antidote against atheisme* (1653a), *Enthusiasmus triumphatus (Enthusiasm Defeated)* (1656), and *The immortality of the soul* (1659). The period culminated in 1662 with the appearance of *A collection of several philosophical writings of Dr. Henry More*. This incorporated the three earlier prose works (the books for which More is now best known), the *Conjectura cabbalistica* (1653b), and More's correspondence with Descartes.

From 1662 until his death, More completed three main projects in philosophy: Latin summaries of his views on ethics (*Enchiridion ethicum (Handbook of Ethics)* 1667) and metaphysics (*Enchiridion metaphysicum (Handbook of Metaphysics)* 1671); the first volume of *Divine dialogues* (1668), the most accessible presentation of his proofs of God's existence, his account of the natural world, and his theodicy; and the translation of his English philosophical works into Latin (in volume 2 of his *Opera omnia*). These were labours of codification more than of inquiry; as Ward suggests in an unpublished manuscript, in this third period More turned towards theology, proving the 'Truth and Nature of *reveald Religion* as before of *natural*' (Gabbey 1982: 222). More's theological works of philosophical interest include *An explanation of the grand mystery of godliness* (1660), *A modest enquiry into the mystery of iniquity* (1664), and the second volume of *Divine dialogues* (1668).

More remained a fellow of Christ's until his death. He consistently refused to consider larger and more prestigious responsibilities such as the mastership of his college (a position filled by Cudworth) and the provostship of Trinity College Dublin. More's second home, where he often rushed as soon as term time ended, was Ragley, north of Oxford, the estate of his friend Anne Conway. More's correspondence with Conway, published in *The Conway Letters*, is an intimate record of a philosophical friendship. When More, consoling Conway on the death of her two-year-old son from smallpox, tells her that 'there is nothing tragicall to those that are truly good' (1930: 169), his theodicy is tested more severely than it ever could be tested in a treatise.

2 Theory of knowledge

More recognized three sources of knowledge: common notions (which he defined as 'whatever is *Noematically* true, that is to say, true at first sight to all men in their wits, upon a clear perception of the Terms'); external sense (including memory, its 'faithfull Register'); and the 'undeniable deductions' of reason ([1659] 1925: 61). More portrays these sources as clear and compelling and he often claims to demonstrate his main conclusions. But he does not expect his arguments to convince a complete sceptic. 'Perfect *Scepticisme*', he wrote, 'is a disease incurable, and a thing rather to be pitied or laughed at, [than] seriously opposed' ([1659] 1925: 59). When he promises to demonstrate that there is a God, he explains, he does not mean that the reader 'shall be forced to confesse that it is utterly unpossible that it should be otherwise'. It is possible, after all, that '*Mathematical evidence* it self may be but a constant undiscoverable Delusion'. But More's arguments 'shall be such as shall deserve *full assent*, and win *full assent* from any unprejudic'd mind' ([1653a] 1925: 4-5).

More sometimes presents arguments in geometric form, drawing attention to their dependence on an ordered list of 'axioms'. Many of these axioms are laid down as noematic truths but, as More makes clear in several places, his axioms are sometimes merely probable. Some of his axioms are rules for the guidance of inquiry: a crucial axiom in the *Immortality*, for example, declares that whatever is clear from common notions, external sense or rational deduction must '*be held undoubtedly true*' when none of the three sources speaks against it ([1659] 1925: 61). In an *Apology* attached to the *Mystery of iniquity* (1664), More lays down several rules for the conduct of a public intellectual concerned to preserve the peace and authority of the established church. A theorem, he cautions, should be embraced 'no farther then as Rational'; we should be 'wary' in asserting its 'absolute reality and truth' (1664: 488).

Though any truth must be clear of contradiction, we can know that something is the case without being able to explain it. ‘*Our Senses*’, for example, ‘do assure us of such things that no faculty can conceive how they are such as *our Senses* warrant them to be’ (1664: 454). This principle plays an important role in More’s defence of the possibility of spirit and the authority of revelation.

Although he admits that thinking is first occasioned by external objects, More thinks it is vital to distinguish between the ‘extrinsecall Occasions’ of our ideas and their ‘adequate or principal Causes’. There are ‘*Innate Notions and Ideas*’ in the mind; the soul is no *tabula rasa* or blank slate. Innate ideas do not ‘[flare] to the *Animadversive Faculty*, like so many *torches* or *Starres*’. There is, instead, ‘an active sagacity in the Soul, or quick recollection, as it were, whereby some small businesses being hinted unto her, she runs out presently into a more clear and large conception’ ([1653a] 1925: 14). Damaris Cudworth (later Masham) quoted these words of More in a letter to Locke. She followed More in suggesting that even though there are no actual representations in the mind innately, the mind has a native power to form conceptions that reach beyond the experience that prompts them. More himself illustrated this dispositional interpretation of innate ideas by comparing the soul to a sleeping musician who can finish a tune after a friend hums the opening notes.

Geometrical ideas are among those that cannot be explained by experience alone; no object of experience approaches the accuracy of our idea of a circle or triangle. Relative notions provide further instances. Cut off half of a pound of lead, More points out, and another pound, at first its equal, becomes its double, without any change in its corporeal makeup. Equal and unequal, he concludes, are not physical affections of matter, from which it follows that they cannot enter the mind through the corporeal organs of sense.

Besides single ideas, there are innate complex ideas (including whole truths or ‘common notions’). The idea of God is More’s leading example, and in the *Antidote*, its innateness plays what seems to be a crucial role in his primary argument for God’s existence. Yet in the *Appendix* added to the second edition of the *Antidote* in 1655, More claims that it is ‘all one’ to his argument whether the idea of God is innate or not. He does go on to insist, however, that the idea is not ‘a crafty Figment of *Politicians*’. It does seem important to More, then, as it had been to Descartes, that the idea of God should not be arbitrary or factitious. But More offers no clear test of factitiousness. To the objection that existence can be derived from the idea of a being which is absolutely evil, he is content to reply that we ‘can easily discover the difference betwixt such arbitrarious and forced Figments and fancies’ as this, and the ‘naturall and consistent *Ideas* of our own Mind’ ([1653a] 1662: 156).

3 The possibility and existence of spirit

The greatest obstacle to the belief in immortality, More believed, was ‘that confident opinion in some’ - he was thinking above all of Hobbes - that ‘the very notion of *a Spirit*’ is ‘a piece of Non-sense and perfect Incongruity in the conception thereof’ ([1659] 1925: 65). In the *Immortality*, More set out to free both spirit in general and the several kinds of spirit from ‘the imputation of either obscurity or inconsistency’ ([1659] 1925: 96).

More defined body as a substance impenetrable and *discerpible* (that is, separable into parts), and spirit as a substance penetrable and *indiscerpible* (not separable into parts). His main argument on behalf of spirit is that every term in its definition is as ‘intelligible and congruous’ as its counterpart in the definition of body. The ‘precise Notion’ of substance (elsewhere defined as any being subsisting by itself) appears in both. ‘And it is as easy to understand what *Penetrable* is as *Impenetrable*’, he writes, ‘and what *Indiscerpible* as *Discerpible*’ ([1659] 1925: 66). If the positive denominations were all on the side of body, it could be said that the intelligibility of spirit, being derived by negation, was second-rate. But each of More’s definitions, as he points out, is partly negative and partly positive.

More’s definition of body is in fact misleading because, according to the *Immortality*, the smallest bodies - atoms or ‘*minima corporalia*’ - are indiscerpible. As the young Isaac Newton wrote in his notebooks, ‘that matter may be so small as to be indiscerpible the excellent Dr More in his book of the soul’s immortality has proved beyond all controversy’ (Newton 1644-5: 341). More’s indiscerpible atoms resist separation into parts, as Newton realized, only because they are so tiny. Despite their small size they remain, in More’s view, ‘purely’ or ‘mathematically’ divisible; it is simply that no force in nature has the power to break them apart. ‘It is of the very Essence of *Matter* to be *divisible*’, More wrote, ‘but it is not at all included in the essence thereof to be *discerpible*’ ([1659] 1925: 77).

Perhaps the most perplexing feature of spirit as More understood it was *extension*: not the extension distinctive of matter, which involves a juxtaposition of parts, but 'a certain *Amplitude of Presence*' that enables the human soul, for example, to be 'at every part [of the body] at once' ([1653a] 1662: 172). Spirit, More reasoned, has the power to move matter, and it must be present wherever that power is exerted. But if the extension of spirit reaches as far as its power, why is spirit not discerpible? In reply More offers an analogy: a 'luminous orb' diffused in all directions from a single and inexhaustible point of light. The spreading light can of course be blocked or contracted by an opaque body, but according, for example, to the Aristotelians (whose hypothesis can be accepted for the sake of unfolding the analogy), it is impossible for the rays to be 'clipt off, or cut from this *lucid point*, and be kept apart by themselves' ([1659] 1925: 71). In a similar way, More proposes, a spirit's 'Centre of Life' gives rise to a 'Secondary Substance' spread around it. The inmost point is an 'emanative cause' of the surrounding extension, one that 'merely by Being, no other activity or causality interposed', produces an effect ([1659] 1925: 74). The effect must therefore be instantaneous. Because the centre of life is an *absolutely* indivisible point, it is, in the end, less perplexing than an atom of matter, whose indiscerpibility coexists uneasily with its (absolute) divisibility.

If spirit is extended, extension cannot be the mark of material substance, as Descartes (for example) proposed. And if God's power is unlimited, God must be extended throughout space. In a letter to More in April 1649, Descartes distinguished between the extension of a substance and the extension of its power. God, he granted, is everywhere, but only in virtue of his power. More replied that the power of God is a mode of God, and because a mode cannot occur apart from the substance it modifies, it is necessary that God is everywhere, a point he repeated years later in the *Enchiridion metaphysicum*.

More defended the intelligibility of both God and finite spirits. He defines a finite spirit, for example, as 'a substance Indiscerpible, that can move it self, that can penetrate, contract, and dilate it self, and can also penetrate, move, and alter the Matter'. More supported the various characteristics in this definition by comparing them to the equally perplexing characteristics of matter. Those who deny spirit, for example, are in no position to quarrel with spirit's ability to move itself, because they themselves take matter to be self-moving (since it obviously moves, and there is, on their view, nothing but matter to get things going in the first place). In the end, we may not understand how spirit moves matter and unites with it. But it is no easier to understand how matter moves matter and how it holds itself together.

More defines God as a being fully and absolutely perfect ([1653a, 1659] 1925: 10, 68). Because necessary existence is among the attributes entailed by full perfection, it follows that God exists. More supports this version of the ontological argument (derived from Descartes) with a second: any being we can contemplate, God included, is either contingent, impossible or necessary. But God is neither contingent (contingency being 'incompetible to an *Idea of a Being absolutely Perfect*') nor impossible (the idea of God 'being compiled of no Notions but such as are *possible* according to the Light of Nature') ([1653a] 1925: 22). Hence God exists, a conclusion confirmed by the natural remorse of conscience, our sense of hope and our feelings of religious veneration. More also employed versions of the cosmological argument and the argument from design: 'No *Matter* whatsoever of its own Nature has any active Principle of *Motion*' ([1659] 1925: 102). Motion is 'superadded' to matter by God, who then conserves it. A 'blind *impetus*' could never produce the admirable order we observe in nature and in ourselves.

There are four main categories of finite or created spirits: seminal forms, the souls of brutes, human souls, and the spirits actuating angels. A seminal form is 'a created Spirit organizing duly-prepared Matter into life and vegetation proper to this or the other kind of Plant' ([1659] 1925: 83). An animal soul is the source of both vegetation and sensation. More's argument for the existence of an incorporeal human soul turns on our awareness of faculties and operations 'utterly incompetible to *Matter* considered *at large* without any *particular* organization' and beyond the capacity of matter (or the 'tumbling of atoms') however organized. These faculties include sense, reason, and liberty, which More defines as the power, notwithstanding external assaults, to cleave to virtue. (Our liberty is known by '*Internal Sense*'. In both the *Immortality* and the *Enchiridion ethicum*, More argues at length against Hobbesian determinism.) The soul is also responsible for the frame of the human body and its vital powers. The human soul as More understands it is therefore not just a mind (as it was for Descartes), but an agent of bodily development and maintenance. More must therefore repudiate Descartes' main argument for dualism. He faults Descartes for inferring a 'real precision' (or real distinction) from a precision in thought. Our vital powers can be conceived apart from our power to reflect and reason, but it does not follow that we have two

souls.

More viewed apparitions (‘speakings, knockings, opening of doors when they were fast shut, sudden lights’ - [1659] 1925: 105) and the efficacy of witchcraft as further proofs of spirit. He contributed reports of apparitions to the 1681 edition of Joseph Glanvill’s *Saducismus Triumphatus*. ‘Those that lay out… well-attested Stories of Witches and Apparitions’, More wrote in a letter included in the volume, ‘*do real service to true Religion and sound Philosophy*’ (Glanvill 1681: 26). The phenomena reported, though not miraculous, cannot be accounted for mechanically (see Glanvill, J.).

4 More and Descartes

More’s initial enthusiasm for Descartes had moderated by the late 1650s, but even as late as 1662 he was able to describe the books in his *Collection* as combining Platonism and Cartesianism. The *Divine dialogues* marks a clear break. The book was published without More’s name, but his earlier books are cited in the dialogues themselves and in a prefatory letter from ‘the Publisher’ - a letter actually written by More. The letter takes note of the author’s ‘*over-plain and open opposing that so-much-admired*…Descartes’ (1668: [x]). Some earlier writers admit that there may be ‘*some few effects*’ in nature that are ‘*purely Mechanicall*’. (Here the publisher refers to the author of the *Epistola ad V.C.* (1662) - the More of the late 1650s.) But the present book, the publisher vows, shows abundantly that ‘*there is no purely-Mechanicall* Phenomenon *in the whole Universe*’ (1668: [xii]). In the ensuing dialogues, Descartes’ views are represented by the character Cupuphon, a ‘zealous, but Airie-minded, *Platonist* and *Cartesian*, or *Mechanist*’. Cartesian views are shown to be incompatible with scripture and serviceable to religion only in so far as they display (against their intention) the limits of mechanism. The publisher does credit Descartes with discovering the ‘most credible Material Causes’ of phenomena; More never abandoned the Cartesian view that matter is of one uniform or ‘homogeneal’ nature, and that change in body is, in itself, nothing but local motion. But the explanatory *causes* of bodily change - the causes that prompt and guide it - were another matter. More had many other quarrels with Descartes; in the fiercely critical *Enchiridion metaphysicum*, for example, he scornfully crowns Descartes prince of the ‘nullibilists’, a party of philosophers who endanger religion by asserting that spirit is nowhere (see Descartes, R. §8).

5 The spirit of nature and the nature of space

Changes in body that cannot be ‘resolved into mere Mechanical powers’ are, according to More, the work of the spirit of nature, the ‘Vicarious power of God upon… matter’ ([1659] 1925: 169; 1662: 13). It is an immaterial substance without sense or thought, pervading the ‘whole matter’ of the universe. It accounts for departures from the laws of mechanism but also, as a ‘natural Transcript’ of those laws (1662: xvi), for matter’s submission to them. Among the phenomena that argue powerfully for the spirit of nature are sympathetic pains, assuagements and cures. But even the falling of a stone or bullet is a sign of its influence because, given only the laws of mechanism, a stone or bullet should recede from the earth instead of falling towards it.

In the *Enchiridion metaphysicum* More presented some of Robert Boyle’s hydrostatic experiments as evidence of the spirit of nature. Boyle, in his *Hydrostatical discourse* (1672), defended a mechanistic interpretation of his results. There Boyle stopped with the claim that More’s ‘hylarchical’ principle is unnecessary, but in his *Inquiry into the vulgarly received notion of nature* (1686) he made broader criticisms (without naming More). Some of Boyle’s points were elaborated by Robert Hooke (1677), who asked, in effect, by what laws More’s spirit operates, since it is surely true, even on More’s view, that it does not simply do what it pleases (see Boyle, R.).

More’s primary argument in defence of immaterial substance in the *Enchiridion metaphysicum* was simply that there is an infinite, substantial space or ‘immobile extension’ really distinct from matter. He proceeded to assign to it many of the names or attributes traditionally reserved for God: infinite, incomprehensible, uncreated, absolutely independent. Infinite space is, he concluded, a ‘rough representation of the divine essence’. Other remarks strongly suggest that it *is* God, or at least an aspect of God. More did caution that the attributes on his list pertain not to God’s ‘life and operation’ but only to God’s presence. He promised to take up the connection between the divine life and the divine presence in a sequel to the *Enchiridion* (which was published as ‘Part One’), but a second part never appeared. The influence of More’s divinized space on the absolute space of Newton is still a matter of debate.

6 Religion

The main theme of More's writing on religion, aimed against atheists on one side and 'enthusiasts' on the other, was the 'Reasonableness' of Christianity. *Enthusiasmus triumphatus* (1656) was a satire on the vice of enthusiasm, which More defined as the 'misconceit of being inspired', or 'moved in an extraordinary manner by the power or spirit of God to act, speak, or think what is holy, just, and true' (1656: 2). Enthusiasm is caused, More argued, by an imagination overpowered by melancholy; its remedy consists in temperance, humility and reason.

The *Mystery of godliness* (1660) was More's major work in defence of the Christian religion. 'A *Mystery*', he explains in the Preface, 'is a piece of Divine knowledge *measurably Abstruse*, whereby it becomes *more Venerable*, but yet *Intelligible* that it may be *Communicable*, and *True* and *Certain* that it may win*firm Assent*, and lastly *very Useful* and *Effectual* for the *perfecting* of the Souls of men, and restoring them to that *Happiness* which they anciently had faln from' (1660: 2). His aim is to represent the fundamentals of Christianity - the faith, plainly propounded in scripture, which is all that is required for salvation. He therefore says little about forms of worship and nothing about church government, but he ends the book with a plea for liberty of conscience. Toleration should be extended to all who believe in God and in punishment and reward in a life to come, provided their beliefs do not call for violations of moral law or disloyalty to their rightful rulers.

List of Works

More, H. (1925) *Philosophical writings of Henry More*, ed. F. Mackinnon, The Wellesley Semi-Centennial Series, New York: Oxford University Press; repr. New York: AMS Press, 1969.(Remains the best anthology of More's philosophical writings. Selections from the *Antidote* and the *Immortality*, together with the final chapters of the *Enchiridion Metaphysicum* as they appeared in the *Saducismus Triumphatus*. Mackinnon's 'Outline Summary of More's Philosophical Theory' on pages 159-71 will be especially useful to anyone reading More for the first time.)

More, H. (1642) *Psychodia platonica; or, a platonicall song of the soul, consisting of foure severall poems; viz., Psychozoia, Psychathanasia, Antipsychopannychia, Antimonopsychia*, Cambridge: R. Daniel.(Verse-arguments for the soul's immortality and pre-existence, its consciousness after death, and its distinctness from other souls.)

More, H. (1646) *Democritus platonissans; or, an essay upon the infinity of worlds out of Platonick principles*, Cambridge; repr. Los Angeles, CA: William Andrews Clark Memory Library, University of California, 1968.(Philosophical poem defending the infinity of worlds.)

More, H. (1653a) *An antidote against atheisme, or an appeal to the natural faculties of the mind of man, whether there be not a God*, London; 2nd edn, with appendix, London, 1655, repr. Bristol: Thoemmes Press, 1997.(Arguments, a priori and empirical, for '*a Being absolutely Perfect*'.)

More, H. (1653b) *Conjectura cabbalistica*, London; repr. Bristol: Thoemmes Press, 1997.(An attempt to lay bare the hidden meanings - scientific, metaphysical, and moral - in the first three chapters of *Genesis*.)

More, H. (1656) *Enthusiasmus triumphatus: or, a discourse of the nature, causes, kinds, and cure, of enthusiasme; written by Philophilus Parresiastes*, London and Cambridge; repr. Los Angeles, CA: Clark Memorial Library, University of California, 1996; repr. Bristol: Thoemmes Press, 1997.(The cause and cure of enthusiasm, or 'misconceit of being *inspired*', in religion and philosophy.)

More, H. (1659) *The immortality of the soul, so farre forth as it is demonstrable from the knowledge of nature and the light of reason*, London and Cambridge; repr. Bristol: Thoemmes Press, 1997; modern edn, ed. A. Jacob, *Henry More. The immortality of the soul*, Dordrecht: Martinus Nijhoff, 1987.(Defends the possibility of spirit and the existence and immortality of an immaterial human soul.)

More, H. (1660) *An explanation of the grand mystery of godliness; or, a true and faithful representation of the everlasting gospel of our Lord and Saviour Jesus Christ*, London and Cambridge; repr. Bristol: Thoemmes Press, 1997.(More's main defence of the Christian religion.)

More, H. (1662) *A collection of several philosophical writings of Dr. Henry More*, London and Cambridge; repr. New York: Garland, 1978.(Contains the *Antidote* and its *Appendix*, *Enthusiasmus triumphatus*, the *Immortality* (with some additions), More's correspondence with Descartes (introduced by an exchange of letters between More and Claude Clerselier), and the *Epistola ad V.C.*, an appraisal of Cartesianism written around 1658 and first published here.)

More, H. (1664) *A modest enquiry into the mystery of iniquity, the first part, containing a careful and impartial delineation of the true idea of antichristianism*, London and Cambridge.(An attack on the idolatry of Catholics.)

More, H. (1667) *Enchiridion ethicum (Handbook of ethics)*, London and Cambridge; trans. as *An account of virtue: or, Dr. Henry More's abridgement of morals, put into English*, London, 1690: repr. New York: The Facsimile Text Society, 1930; repr. Bristol: Thoemmes Press, 1997.(More's only book devoted to ethics. He defines virtue as an intellectual power by which the soul overrules '*Right Reason*', an innate copy of an eternal and immutable morality. The soul is also equipped with a '*Boniform Faculty*', enabling it to 'relish' what is best.)

More, H. (1668) *Divine dialogues…. Collected and compiled by the care and industry of Franciscus Palaeopolitanus*, London, 2 vols.(Volume 1 contains More's most accessible presentation of his proofs of God's existence. Volume 2, which is more theological, contains *A brief discourse of the true grounds of the certainty of faith in points of religion*, where the certainty of faith is said to presuppose certainty of sense and certainty of reason.)

More, H. (1671) *Enchiridion metaphysicum;…. Pars prima: de existentia & natura rerum incorporearum in genere (Handbook of metaphysics;…. Part one: concerning the existence and nature of incorporeal things in general)*, London and Cambridge; repr. Bristol: Thoemmes Press, 1997; modern translation, ed. A. Jacob, *Henry More's Manual of Metaphysics. A Translation of the Enchiridium Metaphysicum with an introduction and notes*, Hildesheim: Georg Olms, 1995, 2 vols.(Latin summary of More's metaphysics.)

More, H. (1675-9) *Opera omnia (Complete works)*, London, 3 vols; repr. vols 2 and 3, Hildesheim: Georg Olms, 1966.(Volume 1 is theological, volumes 2 and 3 philosophical. More's autobiography appears in the *Praefatio generalissima*, volume 2.)

More, H. (1930) *The Conway Letters: The Correspondence of Anne, Viscountess Conway, Henry More, and their Friends, 1642-1684*, ed. M.H. Nicolson, revised edn, ed. S. Hutton, Oxford: Clarendon Press, 1992.(Contains More's correspondence with Conway, with connecting commentary by Nicolson. Hutton adds several letters of philosophical importance, as well as an introduction that is, in part, a brief survey of recent work on More.)

Bristol: Thoemmes Press, 1997.(Includes long passages, translated from the original Latin into English, from More's account of his early life in the general preface to his *Opera Omnia*.)

Moscow-Tartu School

*The Moscow-Tartu School of semiotics (theory of signs) was formed when a diverse group of scholars joined informally from the 1950s to 1980s to provide alternatives to the regnant Soviet approaches to language, literature and culture. Their work develops the linguistics of Saussure, elaborated by Trubetzkoi and Hjelmslev, with its central notions of sign as union of signifier and signified, its distinction between language as system (*langue*) and language as utterance (*parole*), and its analysis in terms of the significant differences between paired equivalent elements in a system (that is, meaning is a matter not of individual elements, but of the relationship between comparable elements). In its early stages members of the Moscow-Tartu School did intricate analyses of lyric poetry and of highly conventional prose works (such as detective stories) using statistical and linguistic methods. They subsequently came to treat art works and other cultural artefacts as the products of 'secondary modelling systems', that is, as elements arranged according to rules that could be seen as language-like and hence accessible to analysis by the procedures of structuralist linguistics. The group shared an interest in Western and pre-Stalinist Russian literary theory - especially in the Russian formalists - and in contemporary linguistics, semiotics and cybernetics. In a time of pervasive intellectual stagnation this loose confederation sought to formulate objective and exact methods for literary scholarship, to republish works of Russian theory that had been repressed from the 1930s to 1950s, and to bring scholarship in the humanities into line with developments in other scholarly fields. During the 1970s prominent members of the group, such as Iu.M. Lotman and B.A. Uspenskii, turned from more theoretical and formalized work to historical studies of culture as a system of semiotic systems.*

1 History: the Soviet context and the rise of semiotics

It is difficult to comprehend the extent to which the policies of the Stalin era hindered the unfolding of academic life. A vigilant censorship, the prescriptions of party congresses, and academic hierarchies established not by intellectual distinction but by survival skills, all combined to discourage critical thinking. Literary scholarship, which had rejected the formalists' attempts to examine literature as a process with its own dynamics and evolution (see Russian literary Formalism), became particularly vulnerable to the demands of the political apparatus. By an irony of cultural history Soviet literary criticism had followed the pattern of innovation and mechanization outlined by the formalist theory of literary evolution: the innovatory and socially committed literary criticism of the nineteenth-century Russian intelligentsia, with its utilitarian view of literature and its understanding of art as a reflection of reality, had become institutionalized and stultifying, a barrier to re-examining the considerable role of literature in Russian society. Yet some disciplines, because of their remoteness, abstractness (linguistics) or technological promise (cybernetics, machine translation) were relatively exempt from the blatant ideologization of academic life. It was to these disciplines that a number of young linguists and 'philologists' (scholars trained in literature, historical linguistics and the history of ideas) turned for support in renewing the humanities. Their fascination with the 'exact methods' and 'objective scholarship' that these disciplines offered ultimately must be understood in the context of the impasse that scholarship had reached.

One of the group's most erudite members, the linguist V.V. Ivanov, would in 1976 trace the rise of Soviet semiotics to the research and theories of Russian and foreign linguists and anthropologists. He specifically identified the psychologist Vygotskii, the cinematographer Eisenstein, the information theorists A.N. Kolmogorov and Claude Shannon (see Information theory), the phenomenologist G.G. Shpet, the philologist M.M. Bakhtin and his colleague V.N. Voloshinov, for their work in reconstructing ancient cultures, in developing theories of the sign and in studying the structures and levels of art. The group's acquisition of these interests was achieved through conferences, informal gatherings and harsh debates between 'physicists' and 'lyricists' in scholarly and popular periodicals.

During the 1950s structuralist analysis slowly began to develop in the Soviet Union, enabled in part by Stalin's 1950 articles on linguistics, which in effect freed the discipline from Marxism's base-superstructure model, licensing the study of grammar and internal laws of language development. Two conferences brought the movement into focus and lent it its particular Soviet concern with cybernetics and information theory: a conference in Gorky (1961) 'On the Application of Mathematical Methods to the Study of the Languages of Artistic Literature' and a symposium in Moscow (1962) 'On the Structural Study of Sign Systems'. The first conference centred around the interest of Academician Kolmogorov in poetry's special potential for conveying information,

but already the papers showed the group’s wide range of interests and approaches: I.I. Revzin used Noam Chomsky’s *Syntactic Structures* (1957) to speculate on the generative structures of literary texts, Ivanov surveyed the achievements of Western structuralism, and A.K. Zholkovskii constructed a genealogy from the works of the Russian Formalists and Sergei Eisenstein. He and Iu.K. Shcheglov would subsequently develop their own ‘generative poetics’, a pragmatic one which focused on the effects generated by the poetic text. The Moscow Symposium, organized by Ivanov, included many of the same participants, but had a more semiotic and less cybernetic focus. Danish semiotic theory (‘glossematics’) (see Structuralism in linguistics §3) offered the promise of interaction between mathematics and semiotics and the possibility of joining the human sciences in a common and exact methodology. A group of papers on art as a semiotic system served as a beginning of the movement beyond verbal texts; papers on etiquette, games, and fortune-telling began the group’s investigations of behaviour and popular culture.

The Tartu presence in the Moscow-Tartu School began with Iu.M. Lotman’s 1963 essay ‘On the Delimitation of the Concept of Structure in Linguistics and Literary Scholarship’ and his *Lektsii po struktural’noi poėtike (Lectures on Structural Poetics)*, which appeared in the first issue of an important new series, *Trudy po znakovym sistemam (Works on Sign Systems)* (1964). As Uspenskii notes in his account of the School’s beginnings, Tartu University brought a different scholarly culture to the movement: more oriented towards canonical literature and the history of ideas, less concerned with linguistics and with popular genres. Tartu University also brought the legacy (however constrained by Soviet reality) of having been the Russian Empire’s most European university, with a tradition of academic autonomy that the other Russian universities had not always enjoyed.

The high point of the Moscow-Tartu School’s activity was its five summer schools (1964-74), held at Kääriku in rural Estonia and in Tartu itself. Described by their participants as ‘carnivalesque’, ‘utopian’ and ‘hermetically sealed’, they centred around lively discussions rather than formal presentations, and their proceedings give brief lists of theses rather than lengthy formal papers. The summer schools brought together the Moscow semioticians and the philology faculty from Tartu, occasional guests (such as Jakobson in 1966), and a number of younger scholars who would continue to develop the school’s themes and concepts after it ceased to exist.

The publications of the Moscow-Tartu School, *Trudy po znakovym sistemam* and other periodicals from Tartu, appeared in shoddy editions whose print runs could not come close to meeting the domestic and international demand for them. Their opponents in Soviet academic life published in much more widely circulated publications and levelled a consistent series of charges against the semioticians, as Peter Seyffert has noted: that semiotics was mere fashion, formalism couched in incomprehensible shibboleths; that its claim to universal applicability could not be sustained; and that ‘mathematical methods’ and ‘exact science’ were promises often unrealized and unrealizable. Certainly the School’s focus on the sign and on language opposed the entrenched Russian view of art as ‘thinking in images’, and certainly its view of culture as a semiotic mechanism rather than a reflection of the means of production, challenged the dogma of Soviet Marxism.

For a variety of internal and external reasons, the Moscow-Tartu School had ceased to function by the mid-1970s. Growing government opposition to intellectual unorthodoxy met with opposition from the Tartu faculty, especially over the invasion of Czechoslovakia in 1968. A number of members of the School emigrated from the Soviet Union and made successful careers in the West. The growing interest of members of the School in questions of culture, which began with studies of typology and increasingly branched out into highly specific research with little attention to theory, led to methodological diffuseness. Nevertheless, the publications of the Moscow-Tartu School continued to appear in periodicals and, increasingly, in book form. By the 1990s Lotman was starring in a highly regarded television series on Russian culture. By another irony of cultural history the Moscow-Tartu School, condemned for neglecting traditional Russian views on literature and society, had become the principal interpreter of both, and of their interrelations for the new Russian Republic. After Lotman died in 1993, this canonization was completed by generous obituaries in the Russian press and by the republication of his semiotic studies.

2 Doctrine: general topics and the work of Uspenskii and Lotman

Because so many of the School’s works were experimental and because their work was so far-ranging, it can be difficult to generalize about their activity. During the two decades of their most intense activity the School tried out many variants of semiotic analysis, moving from an early interest in mathematical modelling, cybernetics and

information theory to work more akin to cultural history and cultural anthropology, two disciplines which were virtually non-existent in the Soviet Union. Nevertheless, a common feature was their use of linguistic models. This was also the case with American, Danish, French and Italian structuralism, but the use of linguistic models stands out even more sharply in the Soviet context because the regnant approach to literature focused on ‘images’, not ‘signs’, and on social determinism rather than on self-regulating sign systems. Against this background the Moscow-Tartu School could be seen as a movement, even though its members were drawing upon a number of different linguistic and semiotic theories: C.S. Peirce’s theory of the sign, Saussure’s understanding of semiotic systems, Danish glossematics, Trubetzkoi’s phonemics, Jakobson’s poetry of grammar and Chomsky’s transformational grammar, to name the most important (see Chomsky, N. §1; Peirce, C.S. §8; Saussure, F. de §2; Structuralism in linguistics §§2-3; Syntax §3). Yet members of the School tended not to pursue linguistic models as exhaustive sets of discovery procedures, as did Jakobson in his studies in the ‘poetry of grammar’: they moved from the mechanisms of meaning-production towards interpretation and beyond the study of closed systems towards contextual studies. As the group moved beyond language to other semiotic systems - ‘secondary modelling systems’, as Uspenskii termed them - the ties to linguistic theory could become tenuous. Nevertheless, even in these later essays one detects an enduring fascination with language, language use (pragmatics), and analytic operations learned from formal linguistics (such as analysis in terms of binary opposition). The problems that the group addressed tended to follow logically from this fundamental appeal to linguistic models: how does poetry convey information with its formal resources, how does poetry use the resources of language to model reality and the artist’s worldview, how may other cultural spheres (including social behaviour) can be analysed using the model of linguistic analysis, what is the text that is available for semiotic analysis, how do different cultures in different historical periods use signs differently, what is the impact of such secondary modelling systems (such as literature, art, or the theatre) upon human cognition and behaviour? The logic of their methodology did not, however, lead them into exploring deeply such subjects as ‘the death of the author’ (who would become a ‘guest of the text’ for such French semioticians as Roland Barthes) or the theory of tropes. Unlike Western structuralists and post-structuralists, the Moscow-Tartu group tended to view the text as a unity, however multilayered and however rich its resources for generating interpretations. Language retained for them its ability to represent reality, complexities of coding notwithstanding; and the human subject was inevitably seen as the constitutor, or at least the user, of codes, more than constituted by them. In this the Moscow-Tartu semioticians, especially those who worked on such canonical figures as Pushkin and Gogol’, contributed a semiotic version to the traditional Russian heroic portrayal of authors and to the traditional Russian veneration of high cultural texts.

Members of the School did innovatory work on many subjects: on various aspects of semiotic theory and on text theory, on mythology and the reconstruction of ancient symbol systems (Ivanov, V.N. Toporov, E.M. Meletinskii, D.M. Segal), on musical semiotics (B.M. Gasparov) and on lyric poetry (Zholkovskii, Revzin, Ivanov). Borrowing a favourite technique from the School’s analytic procedures, description by analysis of pairs of equivalent elements in a system, one may treat the group’s concerns by focusing on the work of two leading members, one from each centre: Iu.M. Lotman, by training as a literary scholar and intellectual historian (he had studied in Leningrad with surviving formalists) and B.A. Uspenskii, by training as a linguist and Slavic philologist (he had studied briefly in Denmark). Lotman’s primary research area was Russian literature and culture of the 1780s to 1830s; Uspenskii’s was the Russian language of the late medieval period and of the eighteenth century, although each ranged far afield in search of telling instances and challenging sign systems. By the late 1960s, however, each had moved towards the interests of the other, towards the investigations of ideology and point of view that marked Lotman’s early work, towards studies of multiple linguistic codes that had interested Uspenskii, and some of their best work was collaborative.

Lotman’s changing interests may be seen in four studies of Pushkin’s novel in verse, *Evgenii Onegin*. The first (1960) analysed the construction of character in the novel; this piece is richly contextual, relating character development to contemporary trends in Russian thought, but treating the novel as an ‘organic whole’. In 1966 he took a radically different approach in a paper on the artistic structure of *Evgenii Onegin*: here the operative concepts are modelling, a hierarchy of relationships, multiple points of view, system and anti-system, relationships, binary oppositions, and the inevitability of multiple interpretations given the text’s multiplication of segments through the organization of its complex stanzas. Interpretation and the reader’s role in the literary process become prominent, although they are governed by the internal relationships of the text. Lotman published a separate monograph on the novel in 1975. Here he achieves a synthesis of his work in intellectual history, his

semiotic analysis of paired opposition, and his Bakhtin-inspired study of multiple points of view as embodied in multiple discourses. He continues to study relations between the literary text and what lies outside it and the text's potential impact on a reader. In 1980 Lotman's commentaries to the novel treated culture in an anthropological sense, as the rituals, customs and conventions of Pushkin's Russia. But analysis by binary opposition - gentry/folk, Russian/European - remains an operative principle.

Uspenskii's work follows a similar trajectory, moving from the analysis of point of view towards studies of Russian culture in a broad, anthropological sense. His *O semiotike ikony (Semiotics of the Russian Icon)* (1971) subjects the 'language' of icons to linguistic analysis (syntactic, semantic, pragmatic), paying particular attention to the 'internal perspective' of medieval icons, according to which painter and viewer establish their point of view within the painting, not outside it. *Poetika kompozitsii (A Poetics of Composition)* (1970) had treated point of view more generally, and, although terms are not always defined with desirable precision, the book suggests an innovatory alternative to plot-based narratology, namely, the analysis with respect to four levels of point of view (ideological, phraseological, spatial and temporal, psychological).

For Lotman, as for Uspenskii, the text is both a sign (in the secondary modelling system) and a sequence of signs in verbal language. Both continued to focus their attention on problems of communication and point of view. Lotman's *Struktura khudozhestvennogo teksta (Structure of the Artistic Text)* (1970) and *Analyz poeticheskogo teksta (Analysis of the Poetic Text)* (1972) share some of the same problems of definition and focus that appeared in Uspenskii's *A Poetics of Composition*. But Lotman, the literary scholar, pays more attention to linguistic analysis and to information theory (the latter generally used metaphorically) than the linguist Uspenskii. While problems of integration in moving from level to level and in moving from analysis to interpretation are not solved theoretically, these books offer many suggestive ideas and fragments of literary analysis. Lotman's treatment of 'event' in the first book as 'the shifting of a character across the borders of a semantic field', as a transgression, or as the violation of an expectation, has been widely influential in studies of narrative.

From these large synthetic works on artistic texts, Lotman and Uspenskii moved to speculative discussions on an even higher level of synthesis, the typology of culture. In their 1971 essay, 'On the Semiotic Mechanism of Culture', culture becomes a system of sign production marked off from non-culture, a system of constraints and prescriptions. Here they differentiate cultures by modes of sign production and, predictably, Lotman and Uspenskii identify two opposed types of culture: cultures oriented towards expression (which view themselves in terms of an aggregate of texts) and cultures oriented towards content (which see themselves as a system of rules). In a more specific and controversial essay, 'Binary Models in the Dynamics of Russian Culture' (1977), they treat Russian culture as marked by a binary opposition between the 'sacred' and 'profane', an opposition which dictates diametrically opposed modes of behaviour. The same terms, for instance new/old, can in different periods occupy different positions in this hierarchy. Lotman and Uspenskii oppose this binary structure to a European ternary one, in which a neutral middle sphere allows for new systems to develop gradually, not catastrophically.

Subsequent research by Lotman and Uspenskii in the concrete phenomena in Russian cultural history address topics of moral and political significance: lying, theatricality, obscenity, religious dissent, pretenders to the throne and the use of multiple languages. Lotman's penultimate book, *Kul'tura i vzryv (Culture and Explosion)* (1992), published just after the fall of the Soviet Union, returns to speculative semiotic-based historiography to re-examine the relationship of culture to what is outside it and to explore Russia's new possibility of entering the 'European ternary system', with its concomitant development by gradual change as opposed to change by violent overthrow. Lotman's last book, his *Besedy o russkoi kul'ture (Conversations About Russian Culture)* (1994), returns to the turn of the nineteenth century to give a thick description of the daily life and traditions of the Russian gentry - its rituals, fashions and social patterns and the meaning that these had for those who practised them. The principled theoretical argumentation of these books, and their rigorous wide-ranging research and openness to experiment, encompass the main achievement of the Moscow-Tartu School.

Motoori Norinaga (1730-1801)

*Motoori Norinaga was a pivotal figure in Japan's 'Native Studies' or 'National Learning' (*kokugaku*) movement. An accomplished philologist, he helped decipher the idiosyncratic eighth-century orthography of the Japanese chronicle of history and myth, the Kojiki (Records of Ancient Matters). This was part of his broader scholarly project of defining the nature of the ancient Japanese sensitivity or 'heart-and-mind' (*kokoro*). In so doing, he articulated an influential religious philosophy of Shintōand an axiology of traditional Japanese values, which he considered as primarily emotivist and aesthetic.*

The eldest son in a merchant family, Motoori relinquished his business interests to concentrate on scholarly pursuits. In order to support himself he also practised traditional, Chinese-based medicine. Motoori's driving passion, however, was the study of ancient Japanese culture. Although his times were dominated by a fascination with Chinese thought, Motoori gravitated towards the 'Native Studies' movement and its appreciation of, and romanticized return to, the values of pre-Sinified Japanese culture (see Japanese philosophy §7). In this regard he felt himself to be the disciple of Kamo no Mabuchi (1697-1769), even though he had only once met the latter in person.

Motoori was also a devout follower of Shintō, believing his own birth to have been the answer to his parents' prayer to the gods. The early Native Studies scholars such as Kamo no Mabuchi had often specialized in the historical philology necessary for studying Japan's most ancient texts, primarily literary or poetic. Because of his religious interests, however, Motoori applied his philological expertise to interpreting the *Kojiki (Records of Ancient Matters)*, a text written in an experimental, short-lived orthography that had been virtually unintelligible for a millennium. Motoori believed the *Kojiki* contained the actual accounts of creation. For four decades, therefore, he analysed the text line by line, translating it into language intelligible to the ordinary reader of his own day.

The connection between Motoori's religious and aesthetic theories lay in his understanding of *kokoro* and its relation to both language and reality (see Kokoro). Motoori argued that the ancient Japanese believed in the self-expressive character of things. In human beings, the *kokoro* is the responsive centre of both emotions and intellect. According to his interpretation of the classical Japanese world view, however, things and words also have *kokoro*. Having a 'genuine *kokoro*', the person is touched by the '*kokoro* of things', thus activating the spiritual and poetic 'power of words' (*kotodama*). If the audience lets themselves be touched by those words with a pure heart, they encounter the *kokoro* of the original expressive event. In short, language is ideally not simply a human product, but the outgrowth of a special resonance among the involved persons, things and words.

This view of ideal expression was intimately related to Motoori's reverence for the *Kojiki*. He believed the tradition that the *Kojiki* was a literal transcription of the ancient Japanese oral tradition, which itself supposedly went back to the original words spoken at the time of creation and arising out of the *kokoro* of that moment. Therefore, if his philological studies could recapture those words, Motoori believed he could, in effect, ritually participate in the re-enactment of creation.

Of course, such a cosmogony necessarily privileged ancient Japan, its language, its gods and the role of its emperor as the intermediary between the gods and humanity. If those claims about origins seemed incredible, Motoori argued, that very incredible appearance only made their truth more likely. The more rationalistic accounts of China (or the West) were suspect precisely because they better met human standards of reasoning; generations of narrators could have corrupted the miraculous facts to make them more acceptable to human reason. Motoori argued that the sacred should inspire awe rather than rational appreciation. Because the *Kojiki* had been written in an orthography that had quickly become unintelligible to the ancients, its account preserved the irrational character of the miracle of creation (see Creation and conservation, religious doctrine of).

Although Motoori himself might not have been an ultranationalist, his account of Japan in world history lent itself to such a world view. Shortly after his death, the Native Studies movement took a more ethnocentric and nationalistic turn. In that way, Motoori's Shintōphilosophy became intertwined with both national and international political agenda.

In his theory of poetics, Motoori focused on the role of aesthetic community, the culture that both articulates and serves as audience for literary expression (see Aesthetics, Japanese). In this respect, he regarded the culture of the Heian court (794-1185) to be the zenith of aesthetic culture. According to Motoori, the genuine *kokoro* of the ancient period was best expressed when there were elaborate rules and a common aesthetic regimen governing the interaction of writer and audience. Such a context, he believed, could generate a heightened sensitivity, subtlety and elegance.

In conclusion, through his philological studies, his formulation of Shintōthought and his detailed theory of poetics, Motoori articulated many principles that continue to be influential in Japanese attempts at cultural or ethnic self-understanding.

Mozi (5th century BC)

Mozi was the first philosopher to question the ideas of Confucius. Scholarly debate centres around the issue of whether Mozi was a 'weak' or a 'strong' utilitarian, an 'act' or 'rule utilitarian', and whether he was a 'language utilitarian' or rather placed the religious authority of a personalized Heaven at the centre of his system. He is noteworthy for being the first thinker to develop a tripartite methodology for verifying claims to knowledge and for attacking the Confucian emphasis on ritual and the centrality of the family as the basis for social and political action.

Little is known about the life of Mozi (otherwise known as Modi or Zi Mozi (the Master Mozi)) except what is recorded in later, apocryphal stories, and scholars are even unsure what his name 'Mo' means or designates. Although he is credited in the 'Treatise on Bibliography' in the *Hanshu (History of the Former Han Dynasty)* with being a member of the aristocratic elite of *daifu* rank in the state of Song, some argue that 'Mo', literally 'black ink', refers to the fact that he was a carpenter of low social status; others claim that he was at some time a convict and branded on the face.

Mozi elaborated ten theses in opposition to Confucian doctrine, now found in the book *Mozi*, which contains all that is left of writings from the Mohist tradition. These theses are 'elevating the worthy', 'conforming with superiors', 'universal love' (also interpreted as 'concern for everyone' and 'impartial love'), 'rejecting aggression', 'thrift in use', 'thrift in funerals', 'heaven's will' (or intent), 'elucidating ghosts', 'rejecting music' and 'rejecting destiny'.

Mozi gathered numerous disciples, founding a sect organized on military lines with a single designated leader who had the powers of life and death over his followers. The Mohists specialized in defensive warfare and hired themselves out as experts to rulers of cities under attack. Towards the end of the Warring States period the Mohists may have divided into three separate groups, each of which criticized the others as being heretical; yet all were deeply involved in defending their master's original vision from attack by contemporary philosophers, producing a second major stage of philosophical theorizing.

Severely damaged, Mohist writings were almost totally ignored throughout Chinese history until restored by the Qing scholar and official Bi Yuan (1730-97). Since then, the greatest effort has gone into rediscovering and interpreting later Mohist thought, with its forays into disciplines now identifiable as logic, ethics and science, especially geometry, optics, mechanics and economics. This later Mohist corpus, written in three stages - 'Expounding the Canons', the 'Canons' and 'Explanations', and 'Names and Objects' - developed a rigorously logical, rational and systematic discourse for determining the three sources and four kinds of knowledge, eliminating the grounding of the philosophy in the divine.

Mujō

A Japanese word originating in Buddhism, mujō *means impermanence, transience or mutability. It characterizes all phenomena of experience, but is especially significant for human endeavours to achieve happiness. In the Buddhist analysis of existence, all things arise and perish through dependent origination; they are impermanent, without substance and continually subject to change. This presents human beings with an imperative existential problem, for they ignore or fail to realize the pervasiveness of impermanence. Endeavouring to secure lasting satisfaction, they cling to what is transient and mutable. The result is suffering, the unsatisfactory nature of ordinary - unenlightened - human existence.*

The problem of impermanence is fundamental to Buddhism from its inception, but interpretations of the concept varied with the evolution of other doctrines, most notably the Mahāyāna *notion of emptiness. The indigenous Japanese sensitivity to the transience of life and nature interacted with Buddhism to articulate, often in aesthetic terms, not only the threats but also the contributions of impermanence to meaningful human existence. The most thorough examination of* mujō *is offered by the Zen Buddhist Dōgen, who in his exposition of the radical temporality of existence as being-time identifies the full realization of impermanence with Buddha-nature or enlightenment.*

1 The problem of impermanence

Mujō is the Japanese word for the Buddhist concept of impermanence (the corresponding Sanskrit term is *anitya*). The traditional Buddhist statement of impermanence is ‘all conditioned things are impermanent’, meaning that they arise, pass away and are subject to change (see Momentariness, Buddhist doctrine of). *Mujō* may thus be translated as ‘transience’ or ‘mutability’. The two Chinese characters making up the word literally mean ‘without constancy’, which further indicates the possible irregularity of change and implies a spatial sense of instability. *Mujō* can also mean evanescence; things may be so fleeting as to have only a tenuous, dreamlike existence.

Originally, the concept of impermanence was descriptive of all experienced phenomena. In the early Buddhist formulation of the fundamental doctrine of dependent origination (*pratītyasamupāda*), all things arise and cease dependent upon causes or conditions. All existence is thus impermanent and nonsubstantial. Importantly, a person has no permanent self but is only a stream of changing interdependent factors. These claims are made on the basis of a close inspection of experience, including meditative states.

The primary implication of impermanence - the problem it presents - is that ordinary ways of seeking satisfaction or meaning in human life are ultimately unsatisfactory and induce suffering (*duḥkha*). That is, human beings mistakenly formulate the concept of a permanent self and seek lasting and secure satisfaction through it and its attachment to things, all of which - self, satisfactions, attachments and things - are actually transient and mutable, hence undependable. The continual pursuit of these dependent and undependable satisfactions is *saṃsāra*; in contrast, *nirvāna* is nondependent or unconditioned (see Nirvāṇa).

The cause of suffering, however, is not impermanence *per se* but ignorance of ‘things as they are’, for example in their conditional arising and impermanence, and the disposition to seek satisfaction through attachments or dependencies. Since the causes of suffering arise conditionally, they too are impermanent and removable. Their elimination, however, requires a thorough transformation of one’s whole person. A key factor in this is the existential awareness of impermanence, for as it deepens so too does the realization of the futility of attachments and the motivation for release from them (see Suffering, Buddhist views of origination of).

2 Background developments in Buddhism

To enhance awareness of impermanence, the scholastic Buddhism that evolved in the centuries following the Buddha’s death (*circa* 483 BC) postulated a theory of moments as part of an analysis of things into their ultimate, atomistic constituents (*dharma*). The Sautrāntika, for example, dissolved the apparent temporal durations of ordinary experience into a succession of discrete, virtually durationless moments, resulting in such a discontinuous conception of change that it raised serious problems in accounting for dependent origination. The Sarvāstivāda theory, on the other hand, attempted to account for continuity by arguing - surprisingly for Buddhists - that all *dharmas* are unchanging real existents at all times and change is mere appearance. Other disputes arose over

theories that tried to mitigate the problem of impermanence by introducing a permanent self, principle, or transcendent form of the Buddha. Since impermanence was associated with *saṃsāra*, *nirvāṇa* was often viewed as permanent.

Mahāyāna Buddhism sought to avoid such controversies by reformulating the nonsubstantiality originally implied by impermanence and dependent arising through the more spatially derived notion of emptiness (śūnyatā) (see Buddhist concept of emptiness). This occurred especially in the Perfection of Wisdom literature (*circa* 100 BC-AD 500) and the works of Nāgārjuna (*circa* AD 150-250). Emptiness means lack of any independent self-nature or defining essence. Everything exists only in relative interdependence, and linguistic distinctions cannot be assumed to designate independently real or substantially existing referents. This empties all ontological categories of any claims to ultimacy, and thus of anything to which one could form attachments.

The emptiness of all conceptual designations means that impermanence and permanence are relatively dependent and neither can be taken as describing the true nature of things. The *Heart Sutra* (*circa* AD 350), for example, states this in the language of nonduality as all *dharmas* marked with emptiness are equally not produced and not destroyed. The distinctions between past, present and future are likewise relatively dependent and not absolute. Dependent origination itself is consequently not conceived in temporal terms of arising and passing away but rather as relative interdependence, or emptiness. Nāgārjuna argues that arising, abiding and perishing are like an illusion or dream. While the language of impermanence may have practical usage at the conventional level, it is not descriptively true, as was posited in early Buddhism, of things as they are.

The lack of defining essence or self-nature in temporal concepts led to relational theories of time in China such as the Tiantai notion of ‘three thousand worlds in one instant of thought’ and the Huayan conception of ‘ten ages’. The ten ages are the present, past and future to each of the three time periods of past, present and future, together with their inclusion in one instant. That is, each moment is interdependently related to a vast field of time, and all time originates interdependently with each moment. The interplay of relations within this temporal field, which seem modelled on spatial relationships, are elaborately explained to show how each time is what it is in relation to all other times, and yet is just itself right now. In Huayan terms, the times interpenetrate each other but do not obstruct each other (see Buddhist philosophy, Chinese).

The actual aim of such metaphysical theories is to return one to spontaneous and harmonious participation in the immediate dynamics of experience, free from delusory mediation, by substantializing concepts and dispositional striving. Impermanence is still conjoined with dissatisfaction and suffering if one holds to a linear conception of time as sequential arising and passing away, but this is only a partial understanding which is to be supplanted by a holistic, relational view of time in light of emptiness.

3 Japanese affirmation of impermanence

The Japanese have often viewed impermanence not only as a problem but also as a fundamental condition contributing to the realization of meaningful human existence. There is a long-standing tradition that emphasizes a deep emotional response to transience and often sees evanescence as heightening the appreciation of beauty.

Affective responses of sorrow or longing can affirm the value and meaningfulness of that which is lost or longed for and, through revealing the shared nature and fate of all things in their transience, allow identification with them. This affective affirmation is enhanced by focusing on the most poignantly beautiful aspects of natural change, typically on such things as autumn leaves, spring blossoms or morning dew, which are beautiful in and through their transience. Evanescence further accentuates this beauty through such qualities as temporal rarity, purity or dreamlike delicacy (see Aesthetics, Japanese).

The aesthetic appreciation of transience stands in complex relation to the primary thrust of Buddhism, for while both see the affective response to impermanence as sorrow, the former treats emotion as revelatory of dimensions of value, whereas the latter views emotion as leading to attachment and enmeshment in delusion. This tension was creatively explored in classical and medieval literature where impermanence was a major theme, and where the modes of temporality could be investigated and expressed through literary form as well as content.

As Japanese responses to transience became more fully informed by Buddhist conceptions in the twelfth to sixteenth centuries, the view of change widened to include such grim aspects as social upheaval and natural

catastrophe. An austere aesthetic of impermanence evolved that admired first the muted and then the cold, desolate beauty associated with the elemental reduction of things through attrition and loss. This aesthetic contributed to theoretical developments in Nō drama, the tea ceremony and linked poetry. The reduction of life to its most extreme conditions reveals the latent, regenerative power of nature and balances perishing and dissolution against arising and creativity. Neither side can exist without the other. In this delicate balance the inconstancy, incompleteness and nonsubstantiality associated with transience become conditions and means for creatively engaging and affirming an impermanent world. As affective responses shade more fully into the Buddhist view, they move from attachment to compassion.

4 Dōgen

The Japanese Zen master Dōgen gives impermanence special prominence by identifying *mujō* (impermanence) with Buddha-nature and offering a descriptive exposition of the radical temporality of existence in terms of being-time. In Dōgen's view, 'The expounding, practising and realizing (enlightening) of impermanence by the impermanent themselves all must be impermanent'. That is, the problem of impermanence is resolved through deepening one's realization of impermanence, which occurs most fundamentally through the practice of Zen meditation.

The identification of impermanence with Buddha-nature means that there are not separate realms where one achieves enlightenment (the realization of Buddha-nature) by escaping or transcending impermanence. Furthermore, Buddha-nature is not to be construed as an essence or attribute which one has or acquires. Rather, it is the occurrence of things as they are, free from the imposition of delusory notions of fixed essences and attachments. As identified with impermanence, it is ongoing, continually occurring and being relinquished in each situation. Experientially, the event of Buddha-nature has an original wholeness and fullness which we reflectively objectify and divide through such distinctions as self and world, being and time, now and then.

Dōgen clarifies the temporality of *mujō* in terms of being-time, stating that 'time, just as it is, is being, and being is all time'. Time and being are inseparable; there is only temporal existence. This reaffirms the nonsubstantiality, or emptiness, of all things through their temporality. Things are better understood as events taking place as constituents of the interrelational temporal-spatial field of an occasion.

Dōgen offers two primary characterizations of the temporality of being-time: right now (*nikon*) and seriatim passage (*keireki*). The former is the immediate presence of events as they are within the temporal occasion, seen in discontinuity with the before and after of other times. It has a dimension of constancy as it is 'always' right now, but it is not like a point on a line or a container within which things occur. Such views, according to Dōgen, are inadequate to lived experience and contribute to the separation of time from being, and from oneself, which results in the problem of impermanence.

Each present occasion can also be viewed in its timefulness, that is, in its continuity with other times, their relations contributing to what it is as in the Huayan view. Seriatim passage indicates this continuity or interdependency with the extended field of other times. Dōgen depicts these interrelations as multidirectional, but unlike Huayan, he presents his views through descriptions of the temporality of experience rather than through metaphysical speculation.

Principally through renewed interest in Dōgen by twentieth-century Japanese philosophers, most notably of the Kyoto school (see Kyoto School), the concept of *mujō* has begun to enter comparative discussions with Western views of temporality and time.

Mulla Sadra (Sadr al-Din Muhammad al-Shirazi) (1571/2-1640)

Sadr al-Din al-Shirazi (Mulla Sadra) is perhaps the single most important and influential philosopher in the Muslim world in the last four hundred years. The author of over forty works, he was the culminating figure of the major revival of philosophy in Iran in the sixteenth and seventeenth centuries. Devoting himself almost exclusively to metaphysics, he constructed a critical philosophy which brought together Peripatetic, Illuminationist and gnostic philosophy along with Shi'ite theology within the compass of what he termed a 'metaphilosophy', the source of which lay in the Islamic revelation and the mystical experience of reality as existence.

Mulla Sadra's metaphilosophy was based on existence as the sole constituent of reality, and rejected any role for quiddities or essences in the external world. Existence was for him at once a single unity and an internally articulated dynamic process, the unique source of both unity and diversity. From this fundamental starting point, Mulla Sadra was able to find original solutions to many of the logical, metaphysical and theological difficulties which he had inherited from his predecessors. His major philosophical work is the Asfar (The Four Journeys), which runs to nine volumes in the present printed edition and is a complete presentation of his philosophical ideas.

1 The primacy of existence

Sadr al-Din Muhammad ibn Ibrahim ibn Yahya al-Qawami al-Shirazi, known variously as Mulla Sadra, Sadr al-Muta'allihin, or simply Akhund, was born in Shiraz in central Iran in AH 979-80/AD 1571-2. He studied in Isfahan with, among others, Mir Damad and Shaykh Baha' al-Din al-'Amili, Shaykh-e Baha'i, before retiring for a number of years of spiritual solitude and discipline in the village of Kahak, near Qum. Here he completed the first part of his major work, the *Asfar (The Four Journeys)*. He was then invited by Allah-wirdi Khan, the governor of Fars province, to return to Shiraz, where he taught for the remainder of his life. He died in Basra in AH 1050/AD 1640 while on his seventh pilgrimage on foot to Mecca.

Safavid Iran witnessed a noteworthy revival of philosophical learning, and Mulla Sadra was this revival's most important figure. The Peripatetic (*mashsha'i*) philosophy of Ibn Sina had been elaborated and invigorated at the beginning of the Mongol period by Nasir al-Din al-Tusi, and there existed a number of important contributors to this school in the century before Mulla Sadra. Illuminationist (*ishraqi*) philosophy, originated by Shihab al-Din al-Suhrawardi, had also been a major current (see Illuminationist philosophy). The speculative mysticism of the Sufism of Ibn al-'Arabi had also taken firm root in the period leading up to the tenth century AH (sixteenth century AD), while theology (*kalam*), particularly Shi'ite theology, had increasingly come to be expressed in philosophical terminology, a process which was initiated in large part by al-Tusi (see Mystical philosophy in Islam; Islamic theology). Several philosophers had combined various strands from this philosophical heritage in their writings, but it was Mulla Sadra who achieved a true fusion of all four, forming what he called 'metaphilosophy' (*al-hikma al-muta'aliya*), a term he incorporated into the title of his magnum opus, *al-Hikma al-muta'aliya fi'l-asfar al-'aqliyya al-arba'a (The Transcendent Wisdom Concerning the Four Intellectual Journeys)*, known simply as the *Asfar*.

Mulla Sadra made the primacy of existence (*asalat al-wujud*) the cornerstone of his philosophy. Aristotle (§§11-12) had pointed out that existence was the most universal of predicates and therefore could not be included as one of the categories, and al-Farabi added to this that it was possible to know an essence without first knowing whether it existed or not, existence thus being neither a constitutive element of an essence nor a necessary attribute, and that therefore it must be an accident. But it was Ibn Sina who later became the source for the controversy as to how the accidentality of existence was to be conceived. He had held that in the existence-quiddity (*wujud-mahiyya*) or existence-essence relationship, existence was an accident of quiddity. Ibn Rushd had criticized this view as entailing a regress, for if the existence of a thing depended on the addition of an accident to it, then the same principle would have to apply to existence itself. This was merely an argument against the existence-quiddity dichotomy, but al-Suhrawardi had added to this another argument, asserting that if existence were an attribute of quiddity, quiddity itself would have to exist before attracting this attribute in order to be thus qualified. From this, al-Suhrawardi deduced the more radical conclusion that existence is merely a mental concept with no corresponding reality, and that it is quiddity which constitutes reality.

It was this view, that of the primacy of quiddity (*asalat al-mahiyya*), which held sway in philosophical writing in Iran up to Mulla Sadra's time. Indeed, Mir Damad, Mulla Sadra's teacher, held this view. However, Mulla Sadra himself took the opposite view, that it is existence that constitutes reality and that it is quiddities which are the mental constructs. By taking the position of the primacy of existence, Mulla Sadra was able to answer the objections of Ibn Rushd and the Illuminationists by pointing out that existence is accidental to quiddity in the mind in so far as it is not a part of its essence. When it is a case of attributing existentiality to existence, however, what is being discussed is an essential attribute; and so at this point the regress stopped, for the source of an essential attribute is the essence itself.

2 The systematic ambiguity of existence

A concomitant of Mulla Sadra's theory that reality and existence are identical is that existence is one but graded in intensity; to this he gave the name *tashkik al-wujud*, which has been usefully translated as the 'systematic ambiguity' of existence. Al-Suhrawardi, in contrast to the peripatetics, had asserted that quiddities were capable of a range of intensities; for example, when a colour, such as blue, intensifies it is not a new species of 'blueness' which replaces the old one, but is rather the same 'blue' intensified. Mulla Sadra adopted this theory but replaced quiddity with existence, which was for him the only reality. This enabled him to say that it is the same existence which occurs in all things, but that existential instances differ in terms of 'priority and posteriority, perfection and imperfection, strength and weakness' (making reality similar to al-Suhrawardi's Light). He was thus able to explain that it was existence and existence alone which had the property of combining 'unity in multiplicity, and multiplicity in unity'.

Reality is therefore pure existence, but an existence which manifests itself in different modes, and it is these modes which present themselves in the mind as quiddities. Even the term 'in the mind', however, is merely an expression denoting a particular mode of being, that of mental existence (*al-wujud al-dhihni*), albeit an extremely attenuated mode. Everything is thus comprehended by existence, even 'nothingness', which must on being conceived assume the most meagre portion of existence in order to become a mental existent. When reality (or rather a mode of existence) presents itself to the mind, the mind abstracts a quiddity from it - being unable, except in exceptional circumstances, to grasp existence intuitively - and in the mind the quiddity becomes, as it were, the reality and existence the accident. However, this 'existence' which the mind predicates of the quiddity is itself merely a notion or concept, one of the secondary intelligibles. It is this which is the most universal and most self-evident concept to which the Aristotelians referred, and which al-Suhrawardi regarded as univocal. But in reality there are not two 'things', existence and quiddity, only existence - not the concept, but the reality - and so 'existence' cannot be regarded as a real attribute of quiddity; for if this were possible quiddity would have to be regarded as already existent, as al-Suhrawardi had objected.

3 Substantial motion

Another of the key properties of existence for Mulla Sadra is its transubstantiality, effected through what he termed motion in substance (*al-haraka fi'l-jawhar*) or substantial motion (*al-haraka al-jawhariyya*). The peripatetics had held that substance only changes suddenly, from one substance to another or from one instant to another, in generation and corruption (and therefore only in the sublunar world), and that gradual motion is confined to the accidents (quantity, quality, place). They also held that the continuity of movement is something only in the mind, which strings together a potentially infinite series of infinitesimal changes - rather in the fashion of a film - to produce the illusion of movement, although time as an extension is a true part of our experience. What gives rise to movement is an unchanging substrate, part of the essence of which is that it is at an indefinite point in space at some instant in time; in other words, movement is potential in it and is that through which it becomes actual. Mulla Sadra completely rejected this, on the grounds that the reality of this substance, its being, must itself be in motion, for the net result of the peripatetic view is merely a static conglomeration of spatio-temporal events. The movement from potentiality to actuality of a thing is in fact the abstract notion in the mind, while material being itself is in a constant state of flux perpetually undergoing substantial change. Moreover, this substantial change is a property not only of sublunary elemental beings (those composed of earth, water, air and fire) but of celestial beings as well. Mulla Sadra likened the difference between these two understandings of movement to the difference between the abstracted, derivative notion of existence and the existence which is reality itself.

Existence in Mulla Sadra’s philosophical system, as has been seen, is characterized by systematic ambiguity (*tashkik*), being given its systematic character by substantial motion, which is always in one direction towards perfection. In other words, existence can be conceived of as a continual unfolding of existence, which is thus a single whole with a constantly evolving internal dynamic. What gives things their identities are the imagined essences which we abstract from the modes of existence, while the reality is ever-changing; it is only when crucial points are reached that we perceive this change and new essences are formed in our minds, although change has been continually going on. Time is the measure of this process of renewal, and is not an independent entity such that events take place within it, but rather is a dimension exactly like the three spatial dimensions: the physical world is a spatio-temporal continuum.

All of this permits Mulla Sadra to give an original solution to the problem which has continually pitted philosophers against theologians in Islam, that of the eternity of the world. In his system, the world is eternal as a continual process of the unfolding of existence, but since existence is in a constant state of flux due to its continuous substantial change, every new manifestation of existence in the world emerges in time. The world - that is, every spatio-temporal event from the highest heaven downwards - is thus temporally originated, although as a whole the world is also eternal in the sense that it has no beginning or end, since time is not something existing independently within which the world in turn exists (see Eternity).

4 Epistemology

Mulla Sadra’s radical ontology also enabled him to offer original contributions to epistemology, combining aspects of Ibn Sina’s theory of knowledge (in which the Active Intellect, while remaining utterly transcendent, actualizes the human mind by instilling it with intellectual forms in accordance with its state of preparation to receive these forms) with the theory of self-knowledge through knowledge by presence developed by al-Suhrawardi. Mulla Sadra’s epistemology is based on the identity of the intellect and the intelligible, and on the identity of knowledge and existence. His theory of substantial motion, in which existence is a dynamic process constantly moving towards greater intensity and perfection, had allowed him to explain that new forms, or modes, of existence do not replace prior forms but on the contrary subsume them. Knowledge, being identical with existence, replicates this process, and by acquiring successive intelligible forms - which are in reality modes of being and not essential forms, and are thus successive intensifications of existence - gradually moves the human intellect towards identity with the Active Intellect. The intellect thus becomes identified with the intelligibles which inform it.

Furthermore, for Mulla Sadra actual intelligibles are self-intelligent and self-intellected, since an actual intelligible cannot be deemed to have ceased to be intelligible once it is considered outside its relation to intellect. As the human intellect acquires more intelligibles, it gradually moves upwards in terms of the intensification and perfection of existence, losing its dependence on quiddities, until it becomes one with the Active Intellect and enters the realm of pure existence. Humans can, of course, normally only attain at best a partial identification with the Active Intellect as long as they remain with their physical bodies; only in the case of prophets can there be complete identification, allowing them to have direct access to knowledge for themselves without the need for instruction. Indeed, only very few human minds attain identification with the Active Intellect even after death.

5 Methodology

Even this brief account of Mulla Sadra’s main doctrines will have given some idea of the role that is played in his philosophy by the experience of the reality which it describes. Indeed he conceived of *hikma* (wisdom) as ‘coming to know the essence of beings as they really are’ or as ‘a man’s becoming an intellectual world corresponding to the objective world’. Philosophy and mysticism, *hikma* and Sufism, are for him two aspects of the same thing. To engage in philosophy without experiencing the truth of its content confines the philosopher to a world of essences and concepts, while mystical experience without the intellectual discipline of philosophy can lead only to an ineffable state of ecstasy. When the two go hand in hand, the mystical experience of reality becomes the intellectual content of philosophy.

The four journeys, the major sections into which the *Asfar* is divided, parallel a fourfold division of the Sufi journey. The first, the journey of creation or the creature (*khalq*) to the Truth (*al-haqq*), is the most philosophical; here Mulla Sadra lays out the basis of his ontology, and mirrors the stage in the Sufi’s path where he seeks to control his lower *nafs* under the supervision of his *shaykh*. In the second journey, in the Truth with the Truth, the

stage at which the Sufi begins to attract the divine manifestations, Mulla Sadra deals with the simple substances, the intelligences, the souls and their bodies, including therefore his discussion of the natural sciences. In the third journey, from the Truth to creation with the Truth, the Sufi experiences annihilation in the Godhead, and Mulla Sadra deals with theodicy; the fourth stage, the journey with the Truth in creation, where he gives a full and systematic account of the development of the human soul, its origin, becoming and end, is where the Sufi experiences persistence in annihilation, absorbed in the beauty of oneness and the manifestations of multiplicity.

Mulla Sadra had described his blinding spiritual realization of the primacy of existence as a kind of ‘conversion’:

> In the earlier days I used to be a passionate defender of the thesis that the quiddities are the primary constituents of reality and existence is conceptual, until my Lord gave me spiritual guidance and let me see His demonstration. All of a sudden my spiritual eyes were opened and I saw with utmost clarity that the truth was just the contrary of what the philosophers in general had held.… As a result [I now hold that] the existences (*wujudat*) are primary realities, while the quiddities are the ‘permanent archetypes’ (*a‘yan thabita*) that have never smelt the fragrance of existence.

(*Asfar*, vol. 1, introduction)

Therefore it is not surprising that Mulla Sadra is greatly indebted to Ibn al-‘Arabi in many aspects of his philosophy. Ibn Sina provides the ground on which his metaphilosophy is constructed and is, as it were, the lens through which he views Peripatetic philosophy. However, his work is also full of citations from the Presocratics (particularly Pythagoras), Plato, Aristotle, the Neoplatonists (see Neoplatonism in Islamic philosophy) and the Stoics (taken naturally from Arabic sources), and he also refers to the works of al-Farabi, and Abu’l Hasan al-‘Amiri, who had prefigured Mulla Sadra’s theory of the unity of intellect and intelligible. This philosophical heritage is then given shape through the illuminationism of al-Suhrawardi, whose universe of static grades of light he transformed into a dynamic unity by substituting the primacy of existence for the latter’s primacy of quiddity. It is in this shaping that the influence of Ibn al-‘Arabi, whom Mulla Sadra quotes and comments on in hundreds of instances, can be most keenly felt. Not only is that apparent in Mulla Sadra’s total dismissal of any role for quiddity in the nature of reality, but in the importance which both he and Ibn al-‘Arabi gave to the imaginal world (*‘alam al-mithal*, *‘alam al-khayal*).

In Ibn Sina’s psychology, the imaginal faculty (*al-quwwa al-khayaliyya*) is the site for the manipulation of images abstracted from material objects and retained in the *sensus communis*. The imaginal world had first been formally proposed by al-Suhrawardi as an intermediate realm between that of material bodies and that of intellectual entities, which is independent of matter and thus survives the body after death. Ibn al-‘Arabi had emphasized the creative aspects of this power to originate by mere volition imaginal forms which are every bit as real as, if not more real than, perceptibles but which subsist in no place. For Mulla Sadra, this world is a level of immaterial existence with which it is possible for the human soul (and indeed certain higher forms of the animal soul) to be in contact, although not all the images formed by the human soul are necessarily veridical and therefore part of the imaginal world. For Mulla Sadra, as also for Ibn al-‘Arabi, the imaginal world is the key to understanding the nature of bodily resurrection and the afterlife, which exists as an immaterial world which is nevertheless real (perhaps one might say more real than the physical world), in which the body survives as an imaginal form after death.

Philosophy has always had a tense relationship with theology in Islam, especially with the latter’s discourse of faith (*iman*) and orthodoxy. In consequence, philosophy has often been seen, usually by non-philosophers, as a school with its own doctrines. This is despite the assertions of philosophers themselves that what they were engaged in was a practice without end (for, as Ibn Sina had declared that what is known to humankind is limited and could only possibly be fulfilled when the association of the soul with the body is severed through death), part of the discipline of which consisted in avoiding *taqlid*, an uncritical adherence to sects (see Islam, concept of philosophy in). It is the notable feature of Mulla Sadra’s methodology that he constantly sought to transcend the particularities of any system - Platonic, Aristotelian, Neoplatonic, mystical or theological - by striving to create through his metaphilosophy an instrument with which the soundness of all philosophical arguments might be tested. It is a measure of his success that he has remained to the present day the most influential of the ‘modern’ philosophers in the Islamic world.

Multiculturalism

Multicultural political philosophy explores ways of accommodating cultural diversity fairly. Public policies often have different consequences for members of different cultural groups. For example, given the importance of language to culture, and the role of the modern state in so many aspects of life, the choice of official languages will affect different people very differently. Similar issues arise concerning the cultural content of education and the criminal law, and the choice of public holidays. To avoid policies that create unfair burdens, multicultural theory turns to abstract inquiries about such things as the relation between culture and individual wellbeing, or the relation between a person's culture and the appropriate standards for judging them. Multiculturalism raises related questions for democratic theory also. Culture may be important to deciding on appropriate units of democratic rule and to the design of special mechanisms for representing minorities within such units. Each of these questions is made more difficult in the context of cultures that reject the demands of liberty or equality. The challenge for philosophers is to develop a principled way of thinking about these issues.

1 Multiculturalism and political thought

Political philosophers from Plato to Mill largely managed to ignore the question of culture. The societies in which they wrote enabled them in large part to take it for granted that the appropriate unit about which to ask questions concerning justice or democracy was a society that shared a culture. As a result, problems of justice or democracy were seen as superimposed on a homogeneous community. Although Mill saw nation states as inevitable, he believed that members of smaller cultural groups would readily give up their inherited culture to join other, stronger nations.

Demographic and political changes throughout the twentieth century have made traditional assumptions about the relations between culture and politics largely irrelevant to public life. Almost all of the world's countries now have substantial minorities from more than one culture. As a result, the ideals of political philosophers, whether concerning democracy, justice or membership, must be redeemed in settings very different to those for which they were first proposed.

Different states are multicultural in different ways. Belgium, Switzerland and Canada are federations of different language groups. Australia, Canada and the USA have substantial aboriginal populations. And most developed countries have large but geographically dispersed immigrant populations. Geographical concentration makes federalism and secession viable options for dealing with cultural difference. In its absence, what is needed is some way of building a political culture that does not exclude those who are different.

2 Liberal theories of cultural membership

Theories of cultural rights divide on a number of questions. While not all cultures are individualistic, most prominent views about multiculturalism share a root commitment to the view that culture matters because of its role in individual people's lives. They differ, however, in their detailed accounts of how and why it matters. Three accounts are prominent. First, some have suggested that culture is largely incidental to political life. While this cosmopolitan view does not deny that people have strong cultural attachments, it supposes that the state has no business taking up any sort of stance in relation to them. Instead the state should treat culture in the way many states treat religion, as a private matter on which the state is officially neutral (see Neutrality, political). Ideally people will be able to help themselves to the resources and possibilities of all of the world's cultures. Second, some have assigned each person's own culture an important role, either as an important aspect of identity or as a precondition of that person's ability to develop autonomously. On this view, the demands of justice are the same across cultures, but among those demands is the protection of the cultural conditions essential to individuality. Third, some have claimed that politics is an essential form of cultural expression, and that institutions should be designed to allow cultures to express themselves politically.

Cosmopolitanism is in many ways an attractive ideal, but there is some reason to doubt that it provides a realistic model for organizing political life. Most of the world's people have neither the resources nor the opportunities to move readily between cultures. Perhaps as important, few have any real inclination to do so. In the light of these circumstances and the central role of the modern state in coordinating economic and other activities, states have no

real alternative to adopting policies with significant cultural consequences. Official languages must be chosen and the legal framework within which people go about their affairs defined. Any response to these issues will make it easier for some cultural groups and more difficult for others. While advocates of cosmopolitanism might doubt the long-term significance of such effects, important questions of fairness arise concerning the effects of any such choices.

Multicultural liberals make fairness the starting point for their accounts of cultural policies. They insist that accommodating cultural difference is fundamentally different from discredited policies of segregation that sought to exclude minorities. For example, Will Kymlicka (1995) argues that aboriginal peoples should be given extra resources and political protection in order to enable them to maintain their cultural context. Because that context provides the background against which they are able to become autonomous, the state has a special responsibility to make sure that it is secure. Otherwise they would be unfairly deprived of something others receive free. The only way to protect that interest is to allow them to exclude outsiders from their society. In the same way, boundaries between states should be drawn in such a way as to enable as many people as possible to find themselves with a secure culture (see Nation and nationalism) Within self-governing areas, immigrants may be chosen with an eye to the society’s cultural stability. Others have made parallel arguments emphasizing the extent to which cultural identification provides a secure anchor in a changing world.

Still, any way of drawing boundaries will leave some people as members of dispersed minorities. Kymlicka advocates integrative policies for such groups so that maintaining some of their traditional practices does not pose a barrier to successful participation in the larger society in which they find themselves. Examples of such policies include allowing religious groups special exemptions from common pause days (when most businesses tend to be closed) or providing heritage language classes for the children of immigrants. In the UK, some have advocated extending anti-blasphemy laws to non-Christian religions. On similar grounds, many liberals advocate an inclusive educational curriculum. Such policies are sometimes said to offer advantages for members of the dominant culture as well as for minorities. In the longer term, they may well lead to the disappearance of many aspects of the cultures they aim to protect. As a result, the ultimate consequence of multicultural liberalism may well be the development of a cosmopolitan culture, in which cultural difference has a status little different from that of religion. While such a loss of diversity may be regarded as unfortunate, multicultural liberals defend their policies in terms of the interests of the current generation, and so have no commitment to diversity as such.

For multicultural liberals, cultural rights are always understood as rights that individuals have to certain cultural conditions. They are not rights that cultures have over their members. Those who wish to reject their inherited culture are always entitled to do so, however difficult they may find it. As a result, multicultural liberals insist that illiberal cultural practices are outside the bounds of toleration. While there are sometimes pragmatic and humanitarian grounds for limiting the use of force to eradicate such practices, communities that coerce dissident members are not entitled to support in so doing. Thus, everything from arranged marriages to coerced participation in religious rituals is outside the range of special protection or even toleration, however important they may be to the survival of the cultural context. Rights of exit are important for the same reasons (see Liberalism §3; Toleration §2).

Differing conceptions of property rights also complicate liberal attempts to protect minority cultures. Many aboriginal cultures (and some religious groups) have traditionally held land in common. If members wish to leave to join the surrounding society, they cannot take their share of the land with them without endangering the material basis of the culture. In such cases, there may be no way of protecting culture without sacrificing individual liberty.

3 The politics of identity

Advocates of identity politics insist that various forms of membership are far more important than cosmopolitans or multicultural liberals suppose them to be. It is sometimes suggested that cultures, as such, are worthy of respect, and that, as such, they require some form of political expression. So put, such a position is attributed more often to opponents than advocated seriously. But something like it marks a fundamental divide in thought about multicultural politics. For liberals, politics should aim to be fair, and so must be fair in its treatment of cultural difference. For others, politics aims to be expressive, and the suggestion that political institutions could ever avoid being carriers of a particular culture is at best naïve.

Expressivist views of politics and culture lead to a variety of policy suggestions. Many of these aim at ensuring long-term cultural survival, while others are supposed to ensure special political representation for groups whose views have been neglected in the past. The differences between these and the policies advocated by multicultural liberals are sometimes unclear. However, the bases for the claims are very different. In particular, where multicultural liberals insist on treating cultural membership as voluntary and so protect rights of exit, advocates of identity politics sometimes suggest the state has a special responsibility to protect found identities, or at least to tolerate groups that seek to do so. In this they come close to the philosophical position of communitarians, and adapt their political views to accommodate the fact of diversity (see Community and communitarianism).

Identity politics derives some of its appeal from the fact that many of the groups in whose name it is put forward have been treated badly by liberal societies. Perhaps its most important shortcoming is its inability to articulate a philosophical basis that does not apply equally well to cultural practices that have in the past been oppressive, especially to women. This problem is particularly pronounced when it is allied to a commitment to cultural survival as a fundamental political goal. Many of the most important aspects of human self-definition, from religious dissent through choice of sexual orientation, are called into question by the idea that cultural groups have some sort of claim over their members.

Recent developments in world politics have led some to scepticism about the prospects for multicultural societies and to arguments that liberal societies can only survive in the context of a shared culture. Only with a shared culture, it is suggested, will people be able to live together in peace and harmony, and only with a shared culture will there be enough social solidarity to call forth the sacrifices necessary to sustain fair terms of social cooperation. At present, such pessimism seems premature. The psychology of sacrifice is at best very poorly understood. While goodwill and the absence of grudges are surely needed for peaceful coexistence, and familiarity doubtless facilitates cooperation, the relation of these to culture in any more robust sense is unclear. A shared culture bears no clear relation to the more everyday demands of justice. (Were the relationship direct, it is probable that culturally homogeneous countries would have achieved a higher level of justice.) Justice needs a model of citizenship and a civic culture. One possible form such a culture can take is a multicultural world in which people learn to appreciate difference and to respect each other. Such a civic culture is perhaps the best hope for a world made up of multicultural societies.

Multiple-conclusion logic

Ordinary arguments can have any number of premises but only one conclusion. Multiple-conclusion logic also allows for any number of conclusions in an argument, regarding them as setting out the field of possibilities among which the truth must lie if the premises are true. Such an argument counts as valid if it is impossible for all the premises to be true and all the conclusions false. Anything that can be said about premises can now be said, mutatis mutandis, *about conclusions, and much of the interest of the subject comes from exploiting this duality. Putting conclusions on a par with premises reflects the idea that truth and falsity, and likewise acceptance and rejection, are polar notions standing on a par with one another.*

1 Multiple-conclusion arguments

Multiple conclusions can best be understood by analogy with multiple premises. Premises function collectively: a number of premises taken together have a strength which far exceeds the sum of their separate strengths. The very existence of deductive logic turns on this fact, which is not undermined by the fact that a finite number of premises are always equivalent to a single one, namely their conjunction. For this equivalence itself relies on the working of the rule 'From *A* and *B* infer $A \,\&\, B$', understood as involving two separate premises (not one conjunctive one), so it does nothing to establish the redundancy of arguments with more than one premise.

Multiple conclusions also function collectively: a set of conclusions will typically be deducible although no single conclusion is deducible. They are best thought of disjunctively, as setting out the field within which the truth must lie on the assumption that the premises are all true. Just as enlarging a set of premises strengthens them (makes more things follow from them), so enlarging a set of conclusions weakens them (makes them follow from more things): as the field containing the truth becomes larger it becomes less informative. Of course, a finite number of conclusions are equivalent to a single one, namely their disjunction, but this no more makes multiple conclusions redundant than the analogous fact about conjunction makes multiple premises redundant.

The definition of logical consequence or implication is now that a set of premises implies a set of conclusions if it is impossible for all the premises to be true and all the conclusions false. The transitivity of implication is a key property of it, which in conventional single-conclusion logic takes the form of the 'cut' principle; that if a set of premises Γ implies a conclusion *A*, and if Γ, *A* imply *B*, then Γ implies *B*. The corresponding multiple-conclusion principle takes this novel form: if $\Gamma,\ \Theta_1$ implies $\Theta_2,\ \Delta$ for every partition of the set Θ into two disjoint parts Θ_1 and Θ_2, then Γ implies Δ.

Logicians often depict arguments by diagrams in which a horizontal line indicates that the sentence immediately below is inferred from those immediately above, so that the diagram branches upwards from one conclusion. Multiple-conclusion arguments can be represented in a similar fashion, except that now the graph can branch downwards as well as upwards. So (1) shows one variety of 'proof by cases', where one starts with a premise of the form '*A* or *B*' and presents the alternatives as distinct cases as a preliminary to establishing the conclusion by separate, parallel arguments for case *A* and case *B*.

(1) $$\begin{array}{cc} \multicolumn{2}{c}{A \vee B} \\ \hline A & B \\ \vdots & \vdots \\ C & C \end{array}$$

(2) $$\begin{array}{cc} \multicolumn{2}{c}{A \vee B} \\ \hline A & B \\ \hline \multicolumn{2}{c}{A \,\&\, B} \end{array}$$

(1) is untypically simple, for in general the combination of upward and downward branching means that branches which have split may subsequently rejoin, creating circuits. Moreover, it turns out that it is essential to allow for circuits (or some equivalent sophistication) if one is to obtain an adequate variety of arguments. But some circuits are vicious, (2), for example. Much of the mathematical development of the subject has therefore been concerned with finding criteria for a diagram to have a valid pattern, in the sense that any argument which has the same bare layout (that is, abstracting altogether from the sentences involved and paying attention only to the way the steps are arranged relative to one another) is bound to be valid provided its component steps are individually valid. This is a good example of a new concept which, because patterns of single-conclusion argument are so rudimentary by comparison, is scarcely appreciable within the conventional framework.

2 Motivation and applications

Multiple-conclusion logic commends itself to the attention of the philosophical logician because putting conclusions on a par with premises is a natural corollary of acknowledging that truth and falsity are polar notions which stand on a par with one another, and likewise acceptance and rejection. Deduction is no longer tilted towards acceptance alone: an argument regarded as going from premises Γ to conclusions Δ with an eye to acceptance can equally be regarded as going from Δ to Γ with an eye to rejection. The connection can be stated in suitably symmetrical terms, namely that if the argument is valid it is irrational to accept all of Γ and reject all of Δ.

For the mathematical logician the removal of the asymmetry embodied in single-conclusion logic means that some anomalies disappear, and distinctions and results which needed qualification become unconditional. Recall, for example, the conventional way of developing a system of logic. First the semantics is set out, then implication is defined in semantic terms and finally, where possible, it is axiomatized, that is, shown to be equivalent to formal deducibility according to some system of rules of inference. This exposes a deficiency. Evidently the notion of implication can be used to say things about the assignments of truth-values determined by the semantics - for example, that none of them makes certain premises true and a certain conclusion false. But the information that can be conveyed in this way is only a fraction of the whole. For example, there is no way of saying in terms of implication alone whether the set of all sentences is satisfiable or not. And even if all the notions with which logicians work - logical truth, implication, satisfiability and so on - are taken together, the situation is similar. What we would surely like, but do not have, is a logical notion or notions capable of saying all there is to say about the semantics at the level appropriate to sentences.

In a similar vein, Carnap (1943) pointed out that, although one may manage to axiomatize a logic initially given semantically, one can never work back and retrieve the semantics from the axiomatization. For example, any axiomatization which is sound and complete for classical propositional logic will equally be sound and complete with respect to a nonstandard semantics in which, in addition to the classically possible assignments of truth-values, every sentence (and its negation) is simultaneously satisfiable. In short, there is no way, in purely formal deductive terms, of expressing the fact that '$\sim$' signifies negation. The situation is akin to the non-categoricity of theories, whereby a first-order theory of real numbers will also have a nonstandard interpretation in a merely countable domain (see Löwenheim-Skolem theorems and nonstandard models). Those who are rightly concerned about the implications of that notorious result might do well to reflect that things are no better for negation.

Multiple-conclusion logic remedies both deficiencies. Implication is now an adequate vehicle for saying all there is to say about any semantics at the level of sentences, for every fact of the form 'It is (is not) possible for these sentences Γ to be true and those ones Δ false' is expressible by the statement that Γ does not (does) imply Δ. And by using multiple-conclusion rules one can obtain axiomatizations from which the intended semantics can be uniquely reconstructed. For example, one can work back from the rules 'From *A*, $\sim A$ infer' and 'Infer *A*, $\sim A$' to the classical truth table for '$\sim$'.

Multiple-conclusion rules of inference can also provide an elegant alternative to the often complicated rules involving assumptions and their discharge, which characterize natural deduction systems. (1) above illustrates the idea by using a multiple-conclusion rule in place of the natural-deduction rule of $\vee$-elimination. A profound application of this idea can be found in Gentzen's work on 'sequents' if one interprets his sequents metalogically as statements about multiple-conclusion implication, though this was not how Gentzen himself regarded them (see Natural deduction, tableau and sequent systems).

Music, aesthetics of

The aesthetics of music comprises philosophical reflection on the origin, nature, power, purpose, creation, performance, reception, meaning and value of music. Some of its problems are general problems of aesthetics posed in a musical context; for example, what is the ontological status of the work of art in music, or what are the grounds of value judgments in music? Other problems are more or less peculiar to music, lacking a clear parallel in other arts; for example, what is the nature of the motion perceived in music, or how can the marriage of music and words best be understood?

Attempts to define the concept of music generally begin with the fact that music involves sound, but also posit such things as cultural tradition, the fulfilment of a composer's aims or the expression of emotions as essential features of music. Perhaps any plausible concept, though, has to involve the making of sounds by people for aesthetic appreciation, broadly conceived. In deciding what is meant by a musical work, further considerations come into play, such as might lead to the identification of it with a sound structure as defined by a given composer in a particular musico-historical context.

In what sense can a piece of music be said to have meaning? Some hold it has meaning only internally - in its structure as an arrangement of melodies, harmonies, rhythms and timbres, for instance - while others have claimed that its meaning lies in the communication of things not essentially musical - such as emotions, attitudes or the deeper nature of the world. The most popular of these beliefs is that music expresses emotion. This is not to say, however, that the emotion expressed in a work is necessarily experienced by those involved in its composition or performance: composers can create peaceful or furious music without themselves being in those states, and the same goes for the performance of such music by performers. Also, the emotions evoked in listeners seem of a different nature from those directly experienced: negative emotions expressed in music do not preclude the audience's appreciation, and in fact commonly facilitate it. Ultimately, a work's expressiveness should be seen as something directly related to the experience of listening to that work. Music is often said to have value primarily in so far as it is beautiful, its beauty being whatever affords pleasure to the listener. But the quality of a work's expressiveness, its depth, richness and subtlety, for example, also seems to form an important part of any value judgment we make about the work.

1 The concept of music

A fundamental question in the aesthetics of music is 'What is music?', understood as a request for a definition or delineation of the general concept of music. Theorists have adopted a number of different approaches to the question, often depending on their further purposes in asking it. Perhaps the only thing that all theorists agree on is that music is necessarily sound.

The most conservative approach seeks to define music in terms of the standard features of most music, to wit, melody, harmony, rhythm, metre, instruments, voices and tone production; but in addition to being inadequate to a number of modes of contemporary composition - serialism, minimalism, *musique concrète*, computer music, aleatory music - it ignores many practices remote from us in space or time that we acknowledge as musical. A more liberal approach to defining music - a structuralist one - issues in the formula of music as 'organized sound'; though music so conceived need not exhibit the standard features of music noted above, for on this conception something is music in virtue of its intrinsic properties alone. On another approach, which may be termed 'experiential' (or 'phenomenological'), music is any sounds that are heard as music, it then being incumbent on the theorist to say what makes such hearing musical; salient implications of this approach are, first, that natural and accidental sounds may be music, and second, that the status of an item as music is relative to the listener and the occasion of listening.

Attempts have been made to define music as a type of sound-involving activity distinguished by certain cultural or sociological traits, for example, a particular cultural function, such as the accompaniment of ritual or the enhancement of group memory, or particular social relationships, such as apprenticeship. Alternatively, music may be defined in an essentially historical manner as those sound-involving items, activities and practices that have evolved, historically and reflexively, from certain earlier such items, activities and practices, and so on, it being incumbent on the theorist to indicate some non-question-begging way of picking out the musical strand of human

history from all others (for instance, the linguistic one) that are sound-involving.

Finally, one may attempt to characterize music intentionally, from the producer's point of view, by appeal to distinctive aims or purposes on the part of makers of sound. One approach of long standing conceives music as sounds made in order to express, evoke or elicit emotions or feelings. Another conceives it as sound used as a vehicle of communicable but non-linguistic thought. But the most common approach of this kind proposes simply that music is sounds made or arranged for aesthetic appreciation.

If one is concerned to define music as an art, to preserve a measure of objectivity for the status of music, and yet to avoid making music's import necessarily either emotional or intellectual, one could do worse than to accept this last suggestion. However, in order comfortably to cover a wide range of cross-cultural phenomena easily recognized by us as music, but in which we would be hard put to discern a norm of aesthetic appreciation in operation, a more inclusive notion of the aim with which sounds are made must be invoked. The following suggests itself: music is sounds humanly made or arranged for the purpose of enriching experience via active engagement (such as through performing, listening, dancing), with the sounds regarded primarily as sounds. Such a definition looks to be adequate to cover virtually everything intelligibly accounted music.

The proposal accommodates even John Cage's notorious *4′33″*, an ostensibly soundless musical composition. Designating a period of silence is (though a limiting case) an organization of sounds in a given span of time, presumably done here with a view to heightening consciousness. In addition, as the composer clearly envisaged, even a span of time specified as one to be left silent by the performer is inevitably filled with sounds of various sorts originating from the environment in which the piece is performed.

2 The ontology of music

The central question of the ontology of music, in musical domains where the notion of a work - a repeatable and non-occasion-bound musical entity - has purchase, is that of what manner of thing a musical work precisely is.

It is clear that the standard musical work of the Western tradition is not any physical object or event whatsoever. In particular, it is not identical with any performance of it. It is equally not to be identified with any score of it, whether original manuscript or mass-produced copy, for such things are evidently seen and not heard. Furthermore, a musical work generally predates any of its performances, and can survive the destruction of all of its scores. Yet scores and performances remain of great importance: musical works in this tradition are largely defined by the former and experienced through the latter.

If a work of music is not a physical entity, what is it? There are four views on this question with some currency, three of which hold that a musical work is some variety of abstract entity. The first is that a musical work is a set or class of performances. The second is that it is a universal or pure type, such as a sound structure or pattern. The third is that it is a mental rather than an abstract entity, something existing properly in the minds of composers as well as perhaps of their interpreters and audiences. And the fourth is that a musical work is a qualified or contextualized type, akin to other products of culture in being creatable and bound to specific persons, times and places of origin. Finally, it is also possible to take an eliminativist view of musical works, denying that there really are any such things, and recognizing only scores, performances, intentions and associated practices.

Eliminativism aside, of the four views indicated above there are arguably conclusive objections to all but the last. Focusing on the second view, the idea that a musical work is simply a sound structure (or tonal-instrumental structure) confronts grave problems. One is that such a thing does not admit of being created; the total musical structure ultimately settled on by the composer, the upshot of various acts of choosing and arranging tones and instrumentations, already exists as an abstract object within the musical system in which composition takes place, and so cannot be brought into being by the composer. But a more important problem is that, conceived as simply a sound structure, a musical work cannot support the complex of aesthetic and artistic predications justifiably made of it. Two musical works, composed within the same musical system, may be identical in musical structure and yet differ in the aesthetic or artistic features that are ascribed to them, for example, brashness, wittiness or originality. This is due to the different contexts in which they were composed, and the different contexts of correct performance, audition, and understanding that this entrains. Only a view such as the fourth noted above, that individuates musical works more finely - for example, as composer-initiated types whose identity is bound up with person, time and place - can be adequate to musical works as they figure in our experience and description of

them. The act of composing a standard musical work is thus one of the composer indicating, in a specific musico-historical context, a musical structure, so creating the work which is precisely the structure-as-indicated-by-the-composer-in-that-context (see Art works, ontology of §§2-3).

3 Musical performance

A number of questions about the performance of music have received attention. Foremost is ‘What is it to perform?’ or ‘What criteria must be satisfied if a performance can be said to have taken place?’ One issue is whether performing requires a pre-existing work, or whether improvising is not also a kind of performing. Another issue is what sort of intentions a performer must have in order for their actions to count as a performance of such-and-such a work, what sorts of means must be employed, and what success conditions *vis-à-vis* a target audience might also need to be satisfied. The question of what it is to perform a work at all shades readily into the question of what it is to perform a work correctly and of what it is to perform it well. Issues such as these about the nature of musical performance and issues concerning the ontology of music are closely interrelated.

Much discussed is the matter of historical authenticity in performance - both what is required in order to achieve it, and why, or even whether, achieving it is desirable. Writers have variously emphasized the specific sound of original performance, the means of sound production employed, the manner of playing then current, or the physical venue and social circumstances of such performance. Alternatively, authority may be claimed to rest with the composer’s intentions, though this also raises problems: there are officially declared intentions, represented by scores, and privately held intentions; low-order intentions, merely implementational in nature, and high-order intentions, definitive of aesthetic goals; and intentions regarding what is essential for proper performance, in contrast to intentions in regard to achieving optimal performance.

The nature of the interpretation involved in performing has been queried, and compared and contrasted with critical interpretation. The status of musical performance as an art of its own has been explored, as have analogies between performing and other actions, for example, those of quoting, displaying, translating or enacting. The phenomenon of virtuosity has attracted attention, as attaching not only to performances but to works themselves. Finally, issues regarding the recording of music and its effect on the performance and the reception of music are beginning to be widely addressed (see Art, performing).

4 Musical form and musical perception

Questions about the basic form of music and the nature of the perception involved in grasping music at ground level are closely intertwined. For the basic form of music is arguably that in virtue of which it is heard as music, or that which is necessarily tracked in the course of perceiving the music.

Though all agree that music is sound which is organized and apprehended in time and thus that the form of music must be both audible and temporal, there is disagreement on many further points. Some hold the fundamental form of music to be local, and to reside in moment-to-moment connections between small-scale parts, while others hold global form, governing large-scale and temporally distant sections of a piece, to be equally basic. Some regard musical form as *sui generis*, involving irreducible and specifically musical qualities, while others take notions, particularly spatial ones, rooted in other domains - such as balance, proportion, symmetry and overall shape - to apply directly to musical form.

Debate also flourishes concerning the nature of the fundamental musical perception by which musical form is grasped. Some philosophers think registration of even the most basic musical features, such as tones, rhythms, motifs and chords, or at least the experience of musical connectedness and movement requires either a special mode of perception, or the metaphorical projection of concepts not literally applicable to sequences of sound, or the exercise of a species of imagination; others hold such posits to be unnecessary, claiming that ordinary perception is adequate to the phenomena at hand. A compromise position about musical movement may be this: even if such movement fails to result from either metaphorical projection or aural imagining, music is *heard as* moving, most notably in its melodic rise and fall, harmonic progression and rhythmic propulsion, despite failing to contain anything that literally moves in the way it is heard as moving.

Currently there is much empirical work on the cognitive psychology of music worthy of the attention of philosophers, concerning principles of grouping, the grasp of melodic contour, the mechanisms of memory and

attention, and the limits of sensitivity to key relationships. Also of interest is the role of unconscious processing in the perception of music, including assignment by a musical processor of syntactic or semantic structure to music as it is heard.

5 Musical understanding

What does the listener's understanding of music consist in? It is arguably a species of knowing-how, or experiential knowing, as opposed to knowing-that, or propositional knowing. Reflection suggests that understanding music is basically a matter of hearing the music in a certain way, of registering or responding to certain aspects of the music. The understanding of music, in other words, is continuous with perception of music; it is not a matter of technical analysis, causal explanation or discursive construal, but of a certain sort of listening experience (see Art, understanding of §5).

This is not to deny that there are kinds and levels of musical understanding, some of which may essentially involve propositional knowledge, that understanding at any level may be shallow or deep, and that different sorts of music may call for different kinds of understanding. But the ability to describe music in articulate terms is not a *sine qua non* of core musical understanding, even if ability to describe music is requisite for the kind or level of musical understanding appropriate to a teacher or critic.

Still, there is a question of the extent to which the listener's understanding of music is informed by concepts of various sorts, in what manner and with what degree of recoverability by the subject. There is also the issue of how similar the understanding of music is to the understanding of language, and of how the understanding of music relates to the appreciation and evaluation of it.

6 Musical meaning: general

It is common to divide views on the meaning or significance of music into two sorts, autonomist and heteronomist. The autonomist position is that music has no meaning, or else that it means only itself (thus yielding what is sometimes called 'intra-musical' meaning). The heteronomist position is that music has some sort of meaning that is other than the music itself (sometimes denominated 'extra-musical' meaning).

It is difficult to find thinkers whose views wholly exemplify either position. Perhaps Hanslick, who regarded music as essentially just a glorious succession of tones, and who held music incapable of conveying anything more than the dynamic qualities exhibited indifferently by phenomena of various sorts, is closest to a complete autonomist; Schopenhauer, who regarded music as an image of the inner nature of the world and held it to signify the infinite varieties of willing or striving, is perhaps closest to a complete heteronomist (see Hanslick, E.; Schopenhauer, A. §5). Gurney's view, contrary to common belief, is as much heteronomist as autonomist, though he regards music's expression of mental states as detachable from, and less important than, its purely musical beauty or impressiveness (see Gurney, E. §2). Langer's view is substantially heteronomist, postulating that music is symbolic of emotional life, though Langer denies that such symbolism carries as far as individual emotions. The view of Leonard Meyer is substantially autonomist, in that it accords pride of place to embodied meaning, consisting roughly in the implications that musical events have for other musical events in a musical fabric; yet room is also made for designative meaning of an emotional sort, explained as a by-product of the play of expectations involved in sensing the implications for continuation that a musical composition at every point presents (Meyer 1956; 1967).

It seems reasonable to take musical meaning and understanding to be correlative concepts, so that the meaning of a stretch of music would comprise whatever is understood in understanding it. Viewed from that perspective, the question of whether music has any meaning beyond itself becomes that of whether in understanding music we need register or respond to anything more than purely musical events and relationships. The answer to this would seem clearly to be yes; though order and connectedness in purely musical dimensions is the basis of musical discourse, it does not exhaust it, and a comprehending experience of that discourse accordingly goes beyond a grasp of musical relationships *per se*.

7 Musical meaning: expression

The sort of extra-musical meaning in music that has seemed to most observers to be of greatest importance is

expressive meaning, that is, the expression by music of psychological states. The states music has been held to be capable of expressing include emotions, feelings, moods, attitudes and traits of personality.

Philosophical explication of the concept of musical expressiveness must not be conflated with investigation of the grounds or causes of such expressiveness. The identification of factors involved in making music expressive - tempo, timbre, major or minor mode, or similarities between music and vocal utterance, for example - is one thing, and the logical analysis of what musical expressiveness consists in quite another.

The expressiveness of music, though evidently related to the literal expression of psychological states by persons through behaviour, countenance and demeanour, must yet be clearly distinguished from it. Taking emotions as the paradigm states involved, the expression of emotion by a person is a dated occurrence, involving outward manifestations that warrant a reasonable inference to the person's being in the given emotional state, and requires that the person actually feel the emotion being expressed. When, however, a musical passage is expressive of an emotion, the emotion is not an occurrent one, and any inference to emotion felt on the part of the composer would be unwarranted, and probably mistaken; nor is a musical passage literally a behavioural manifestation of any sort. Musical expressiveness, in short, is a property of music, not of individuals who happen to be connected to the music.

The logical distinctness of musical expressiveness and personal expression still allows for a remarkably persistent hypothesis, sometimes called the ‘Expression Theory’ of music, to the effect that the emotion a piece of music is expressive of is always as a matter of fact one that was experienced by the composer, and that the expressiveness of music is always in effect the expression of the composer's own emotion, imparted to the music in the act of composing. But apart from its romantic appeal, the hypothesis has little to recommend it. The composing of music is typically too indirect, intellectually mediated, temporally extended and discontinuous for such a generalization to hold, even roughly. A composer in a sanguine frame of mind can very well write sanguinary music, or the reverse, with this being as comprehensible as the only somewhat more frequent match of music and mood mistakenly posited as universal by the Expression Theory. And talented composers can craft music expressive of a number of emotional states without themselves being in any of them at the time.

The emotional expressiveness of music must also be distinguished from its power to arouse or evoke corresponding feelings in listeners. There are numerous reasons for this, but two of the more important seem to be these. First, the expressiveness of music presents itself as a manifest property of it, or at any rate, something about how it is readily heard, rather than as an inferred power to raise affect in us. And second, the affects that music does produce in us while listening will often differ, in degree, kind and polarity, from those which it is expressive of; if they did not, it would be puzzling both that music expressive of negative emotion was as popular as it was, and that the aesthetic appreciation of expressive music of any sort, which calls for a certain amount of clear-headed attention, was possible at all.

As for what emotional expressiveness in music might consist in, a number of ideas are currently under consideration. They include music's having a sound resembling the behavioural expression of an emotion; music's metaphorically exemplifying some emotion; music's sounding the way some emotion feels; music's presenting the appearances of an emotion; music's corresponding to an emotional state or being seen as suitable to its expression; music's being imagined to be the gestures of an individual experiencing emotion; and music's being hearable as, or as if it were, the personal expression of an emotion. In any event, it seems clear that the expressiveness of a musical passage should be conceived as something not detachable from, or experienceable apart from, the passage that possesses it.

Some theorists who fully acknowledge the expressive dimension of music balk at describing this as a species of musical meaning. Music's expressiveness would only be a form of meaning, they maintain, if in addition to possessing and exhibiting expressive qualities music also referred to, denoted or was otherwise about the emotions or other states corresponding to such qualities. But the issue can be mooted by simply speaking of music's expressive content, rather than meaning (see Artistic expression; Emotion in response to art §§4, 6).

8 Musical meaning: representation

Musical representation means the depiction by music of concrete persons, things or events. This is least problematic for sounds, or objects with characteristic sounds, that music can obviously imitate or approximate. But

the scope of musical representation plausibly extends beyond this to concrete phenomena that can be heard in music, or that a passage of music might be heard as, which hearing may obtain in the absence of notable sonic resemblance between music and the phenomenon in question, but in virtue instead of certain structural parallels or isomorphisms between them.

There is an important distinction between musical depictions that attuned listeners recognize as such unaided, and those that are only so recognized upon provision of a verbal cue or label, but there seems little reason to identify that with the distinction between representational and nonrepresentational music *per se*. The issue has also been raised of whether musical representation requires the composer’s intention to represent the putative subject, and whether this intention must be signalled by a composer-given title, or otherwise publically recorded.

Some have questioned whether even the most explicitly programmatic music is ever truly representational, on the grounds that representation requires more than securing perceptual reference to some object or event, representation being held to require also a characterization of what is referred to or the attribution of predicates to it, which music is claimed powerless to accomplish. But it is not clear either that such a demand is warranted, or, if it is, that music cannot meet it.

Philosophers have also been concerned to assess the importance of such musical representation as there is. It has been asked whether, when a piece of music is representational, its representational aspect must be grasped if the piece is to be understood, whether such music is not sometimes equally enjoyable if its representational aspect is ignored, and whether the representational and expressive properties of music are not often interdependent - in which event, assuming expressive properties are always of artistic moment, the appreciative relevance of the representational aspect of music in such cases would be assured.

9 Musical meaning: other aspects

The expression of mental states and the representation of concrete objects and events by no means exhausts the modes of meaning music has been held to possess. Additional meanings that have been ascribed to music fall mostly into one of two broad categories, metaphysical and sociocultural.

Metaphysical meanings include suggestions of a fairly moderate sort, such as that music symbolizes, in addition to or in lieu of individual psychological states, the sphere of feeling generally (Langer 1942), or that music exemplifies general patterns of continuation, growth or development in the natural world (Beardsley 1981), or that music is capable of modelling states of mind in which truths of human existence stand revealed (Sullivan 1927). Metaphysical meanings of a more radical sort have also been posited: Schopenhauer, for example, thought of music as a direct image of the cosmic will, and Nietzsche viewed music as divulging the pain and suffering at the root of earthly existence.

Cultural meanings are implicated in suggestions to the effect that music possesses ideological content, reflecting or endorsing existing political arrangements or social structures, or moral content, personifying and displaying virtues of character, or that it embodies a society’s attitudes towards sex, reason or religion. Unlike the expressive and representational meanings considered above, meanings of this sort, where justifiably ascribed, may be carried by whole genres of music, or by acts or contexts of presentation, rather than by specific works.

Supporters of broader meanings for music must indicate criteria for the possession of such meanings by music, mechanisms by which music may conceivably effect them, and reasons for holding them to be intersubjectively valid. The more extrinsic the kind of meaning proposed as attaching to music, the more difficult it will be to hold both that the understanding of music requires grasp of such meanings, and that such understanding will be primarily experiential in nature.

10 The value of music

The value of individual pieces of music must be distinguished from the value to a culture of music as a whole - though the latter will likely depend, in various ways, on the former. The artistic value of an individual piece of music may plausibly be identified, in the main, with the intrinsic value of correct experience of it.

Chief among the artistic values of music is presumably beauty - what Gurney labelled simply ‘musical impressiveness’, and what Hanslick regarded as inherent in ‘tonally moving forms’. Musical beauty, it might be

said, is that in virtue of which music is inherently pleasurable to follow, apprehend or contemplate. It is a point of contention whether such beauty is susceptible to explanation in terms of principles, if any, governing the emergence of beauty in other spheres, or is rather uniquely musical (see Beauty).

The other obvious artistic value of music derives from its expressiveness or extra-musical dimension generally. Music seems more valuable the more expressive it is, or the more richly, finely or profoundly it embodies whatever content it possesses beyond the purely musical.

Broadly speaking, views on the value of music divide into views that locate such value primarily in music's presentation of an autonomous world of sound, one whose forms and qualities can be appreciated without reference to those of life, and whose virtue consists in removing one satisfyingly from ordinary human affairs, and views that locate such value primarily in music's reflection of the real world, whose virtue is the effecting of a deeper or more intense immersion in the world, revealing or clarifying aspects of life that ordinarily remain obscure or only dimly grasped.

Stravinsky, I. (1956) *Poetics of Music*, New York: Vintage Books.(Reflects an extreme formalism about music, arguably inconsistent with the composer’s own practice.)
Sullivan, J.W.N. (1927) *Beethoven: His Spiritual Development*, London: Jonathan Cape. (Suggests that some music, such as the last compositions of Beethoven, embodies and communicates to a listener spiritually and cognitively valuable states of mind.)
Tanner, M. (1985) ‘Understanding Music’, *Proceedings of the Aristotelian Society Supplement* 59: 215-32. (Emphasizes a hierarchy of levels of understanding music, with higher levels presupposing lower ones if they are to have any point.)
Tarasti, E. (1994) *A Theory of Musical Semiotics*, Bloomington, IN: Indiana University Press.(A comprehensive work by a leading advocate of semiotics as applied to music.)
Thom, P. (1993) *For an Audience: A Philosophy of the Performing Arts*, Philadelphia, PA: Temple University Press.(Advances a naturalistic understanding of works in the performing arts.)
Toch, E. (1948) *The Shaping Forces in Music*, New York: Criterion Music Corp.(A searching, lesser-known composer’s examination of the bases of musical form, and the special role of movement and connectedness therein.)
Tormey, A. (1971) *The Concept of Expression*, Princeton, NJ: Princeton University Press.(A seminal philosophical analysis, containing a devastating attack on the Expression Theory of music.)
Tormey, A. (1974) ‘Indeterminacy and Identity in Art’, *The Monist* 58: 203-15.(Explores the sort of ontology of music suggested by, or appropriate to, certain modes of avant-garde composition.)
Treitler, L. (1993) ‘History and the Ontology of the Musical Work’, *Journal of Aesthetics and Art Criticism* 51: 483-97.(Explores the relevance of historical scolarship in musicology to questions of musical ontology.)
Walton, K. (1998) *Looking, Listening, Imagining*, Oxford: Oxford University Press.(A collection of essays by a leading aesthetician, some of which bring the author’s doctrine of make-believe to bear on issues about musical understanding and content.)
Wolterstorff, N. (1980) *Works and Worlds of Art*, Oxford: Oxford University Press.(Contains important proposals regarding the ontology and composition of music.)
Zuckerkandl, V. (1956) *Sound and Symbol: Music and the External World*, Princeton, NJ: Princeton University

Press.(A wide-ranging examination of the phenomenon of music, focusing on the paradox of tonal motion and the experience of musical time.)

Zuckerkandl, V. (1973) *Man the Musician*, Princeton, NJ: Princeton University Press.(A sequel to *Sound and Symbol*, focusing on the notion of musicality as exhibited in listening, performing and composing.)

Musonius Rufus (1st century AD)

Gaius Musonius Rufus was a Stoic philosopher who taught in Rome. Active on the margins of political life, he was twice exiled and recalled. His surviving work focuses on practical ethics. Besides his distinctive views on marriage, sexual morality and women's education, Musonius is important for his influence on Epictetus.

Born before AD 30 in Etruria, Musonius was a member of the wealthy equestrian class, not the senatorial aristocracy. He taught in Greek, and his influence in Neronian and Flavian Rome was considerable. After being exiled by Nero for his links to Stoic senators, his fame grew and followers joined him on the island of Gyara. Recalled to Rome at Nero's death, he resumed lecturing and successfully prosecuted the persecutor of a Stoic senator. He was later exiled and recalled again under the Flavian emperors. By the time of his death, probably before AD 100, he had become a symbol of the philosophical life for the Roman aristocracy.

Although Musonius wrote nothing, accounts of many of his lectures were taken down and published after his death. Extracts from twenty-one survive in a late anthology; these and some short quotations and anecdotes are all that remain today. His thought is rooted in the Socratic tradition. Happiness (see Eudaimonia) is the ultimate goal; the human species is defined by its natural rationality and desire for the good. The virtues (see Aretē) include justice, courage, wisdom and self-control (*sōphrosynē*), though emphasis is given to self-control, especially in matters of sex, food and personal adornment. Virtues are understood partly in terms of the traditional craft analogy. Training (*askēsis*) and endurance are emphasized; practical application overshadows theory.

As a Stoic, Musonius held that human nature is essentially rational and that our function is to act in accordance with reason and the providential plan for the world laid down by the gods (see Stoicism). Human reasoning is to be used to support and complement our nature, never to transcend it or transform it. Since women have the same nature as men, they need and deserve the same education. Although their social roles differ, men and women have equal need of philosophy to guide their lives; similarly kings should practise philosophy, though the manual work of farming is held to be the ideal activity for a philosopher.

Musonius advanced the distinctive view that the natural function of sexual activity is only to produce offspring; hence all other sexual relations, heterosexual or homosexual, are improper and reveal a lack of self-control. Even in marriage, sex for pleasure alone is wrong. The goal of marriage is the rearing of many children (abortion and exposure of infants being contrary to nature) and the cultivation of companionship between spouses, which is both a symbol of and the foundation for social relations generally. Though we may suspect the influence of Roman social values on this teaching, Musonius supports his position with arguments based on natural teleology. His central theme is the importance of self-control in the service of a rationally articulated understanding of human nature.

Mystical philosophy in Islam

Mystical philosophy has an intimate connection with the mainstream of Islamic philosophy. It consists of several main strands, ranging from Isma'ili *thought to the metaphysics of al-Ghazali and Ibn al-'Arabi, and with a continuing powerful presence in the contemporary Islamic world. Although mystical thinkers were aware that they were advocating an approach to thinking and knowledge which differed from much of the Peripatetic tradition, they constructed a systematic approach which was often continuous with that tradition. On the whole they emphasized the role of intellectual intuition in our approach to understanding reality, and sought to show how such an understanding might be put on a solid conceptual basis. The ideas that they created were designed to throw light on the nature of the inner sense of Islam.*

1 Mystical philosophy as Islamic philosophy

It is important at the outset to ask what is meant by mystical philosophy in the context of the Islamic philosophical tradition. The term in Arabic closest to the phrase 'mystical philosophy' would perhaps be *al-hikmat al-dhawqiyya*, literally 'tasted philosophy or wisdom', which etymologically corresponds exactly to sapience from the Latin root *sapere*, meaning to taste. As understood in English, however, the term 'mystical philosophy' would include other types of thought in the Islamic context, although *al-hikmat al-dhawqiyya* was at its heart. *Al-hikmat al-dhawqiyya* is usually contrasted with discursive philosophy, or *al-hikmat al-bahthiyya*. Mystical philosophy in Islam would have to include all intellectual perspectives, which consider not only reason but also the heart-intellect, in fact primarily the latter as the main instrument for the gaining of knowledge. If this definition is accepted, then most schools of Islamic philosophy had a mystical element, for there was rarely a rationalistic philosophy developed in Islam which remained impervious to the distinction between reason and the intellect (as *nous* or *intellectus*) and the primacy of the latter while rejecting altogether the role of the heart-intellect in gaining knowledge.

This entry concentrates on those schools which not only include but emphasize *noesis* and the role of the heart-intellect or illumination in the attainment of knowledge. We shall therefore leave aside the Peripatetic school, despite the mystical elements in certain works of al-Farabi, the 'oriental philosophy' of Ibn Sina (Nasr 1996b) and the doctrine of the intellect adopted by the Muslim Peripatetics (*mashsha'un*) in general. Instead, the discussion will concentrate primarily upon the Isma'ili philosophy so closely connected with Hermetic, Pythagorean and Neoplatonic teachings, the school of Illumination (*ishraq*) of al-Suhrawardi and his followers, certain strands of Islamic philosophy in Spain and later Islamic philosophy in Persia and India. However, it would also have to include the doctrinal formulations of Sufism and its metaphysics from al-Ghazali and Ibn al-'Arabi to the present.

2 Isma'ili and Hermetic philosophy

Isma'ili philosophy was among the earliest to be formulated in Islam going back to the *Umm al-kitab (The Mother of Books)* composed in the second century AH (eighth century AD). It expanded in the fourth century AH (tenth century AD) with Abu Hatim al-Razi and Hamid al-Din Kirmani and culminated with Nasir-i Khusraw (Corbin 1993, 1994). By nature this whole philosophical tradition was esoteric in character and identified philosophy itself with the inner, esoteric and therefore mystical dimension of religion. It was concerned with the hermeneutic interpretation (*ta'wil*) of sacred scripture and saw authentic philosophy as a wisdom which issues from the instructions of the Imam (who is identified on a certain level with the heart-intellect), the figure who is able to actualize the potentialities of the human intellect and enable it to gain divine knowledge. The cosmology, psychology and eschatology of Isma'ilism are inextricably connected with its Imamology and the role of the Imam in initiation into the divine mysteries. All the different schools of Isma'ili philosophy, therefore, must be considered as mystical philosophy despite notable distinctions between them, especially, following the downfall of the Fatimids, between the interpretations of those who followed the Yemeni school of Isma'ilism and those who accepted Hasan al-Sabbah and 'The Resurrection of Alamut' in the seventh century AH (thirteenth century AD).

Two of the notable philosophical elements associated with Shi'ism in general and Isma'ilism in particular during the early centuries of Islamic history are Hermetism and Pythagoreanism, the presence of which is already evident in that vast corpus of writings associated with Jabir ibn Hayyan, who was at once alchemist and philosopher. The philosophical dimension of the Jabirian corpus is certainly of a mystical nature, having incorporated much of

Hermeticism into itself, as are later works of Islamic alchemy which in fact acted as channels for the transmission of Hermetic philosophy to the medieval West. When one thinks of the central role of Hermeticism in Western mystical philosophy, one must not forget the immediate Islamic origin of such fundamental texts as the *Emerald Tablet* and the *Turba Philosophorum*, and therefore the significance of such works as texts of Islamic mystical philosophy. Obviously, therefore, one could not speak of Islamic mystical philosophy without mentioning at least the Hermetical texts integrated into Islamic thought by alchemists as well as philosophers and Sufis, and also Hermetic texts written by Muslim authors themselves. It should be recalled in this context in fact that the philosopher Ibn Sina had knowledge of certain Hermetic texts such as *Poimandres* and the Sufi Ibn al-ʻArabi displays vast knowledge of Hermeticism in his *al-Futuhat al-makkiyya (The Meccan Illuminations)* and many other works (Sezgin 1971).

As for Pythagoreanism, although elements of it are seen in the Jabirian corpus, it was primarily in the *Rasa'il* (Epistles) of the Ikhwan al-Safa' in the fourth century AH (tenth century AD), who came from a Shiʻite background and whose work was wholly adopted by later Ismaʻilism, that one sees the full development of an Islamic Pythagoreanism based upon the symbolic and mystical understanding of numbers and geometric forms (Netton 1982) (see Ikhwan al-Safa'). What is called Pythagorean number mysticism in the West had a full development in the Islamic world, and was in fact more easily integrated into the general Islamic intellectual framework than into that of Western Christianity (see Pythagoreanism).

3 Illuminationist philosophy

Perhaps the most enduring and influential school of mystical philosophy in Islam came into being in the sixth century AH (twelfth century AD) with Shihab al-Din al-Suhrawardi, who founded the school of *ishraq* or Illumination. Al-Suhrawardi's basic premise was that knowledge is available to man not through ratiocination alone but also, and above all, through illumination resulting from the purification of one's inner being. He founded a school of philosophy which some have called theosophy in its original sense, that is, mystical philosophy through and through but without being against logic or the use of reason. In fact, al-Suhrawardi criticized Aristotle and the Muslim Peripatetics on logical grounds before setting about expounding the doctrine of *ishraq*. This doctrine is based not on the refutation of logic, but of transcending its categories through an illuminationist knowledge based on immediacy and presence, or what al-Suhrawardi himself called 'knowledge by presence' (*al-ʻilm al-huduri*), in contrast to conceptual knowledge (*al-ʻilm al-husuli*) which is our ordinary method of knowing based on concepts (Ha'iri Yazdi 1992).

In his masterpiece *Hikmat al-ishraq (The Philosophy of Illumination)*, translated by the foremost Western student of al-Suhrawardi, Henry Corbin, as *Le Livre de la Sagesse Orientale (The Book of Oriental Wisdom)*, the Master of Illumination presents an exposition of a form of mystical philosophy which has had a following up to the present day. Based upon the primacy of illumination by the angelic lights as the primary means of attaining authentic knowledge, the school of *ishraq* in fact was instrumental in bestowing a mystical character upon nearly all later Islamic philosophy, which drew even closer to Islamic esotericism or Sufism than in the earlier centuries of Islamic history without ever ceasing to be philosophy. Although the wedding between philosophy and mysticism in Islam is due most of all to the gnostic and sapiential nature of Islamic spirituality itself, on the formal level it is most of all the school of Illumination or *ishraq* which was instrumental in actualizing this wedding, as eight centuries of later Islamic philosophy bears witness (see Illuminationist philosophy).

4 Philosophy in the Maghrib and Spain

The rise of intellectual activity in the Maghrib and, especially, Andalusia was associated from the beginning with an intellectual form of Sufism in which Ibn Masarra was to play a central role. Most of the later Islamic philosophers of this region possessed a mystical dimension, including even the Peripatetics Ibn Bajja and Ibn Tufayl. The former's *Tadbir al-mutawahhid (Regimen of the Solitary)*, far from being a political treatise, deals in reality with man's inner being. Ibn Tufayl's *Hayy ibn Yaqzan (Living Son of the Awake)*, interpreted by many in the West in naturalistic and rationalistic terms, is a symbolic account of the wedding between the partial and universal intellect within the human being, a wedding which results consequently in the confirmation of revelation that is also received through the archangel of revelation, who is none other than the objective embodiment of the universal intellect. Moreover, this mystical tendency is to be seen in its fullness in less well-known figures such as Ibn al-Sid of Badajoz who, like the Ikhwan al-Safa', was devoted to mathematical mysticism, and especially the

Sufi Ibn Sab'in, the last of the Andalusian philosophers of the seventh century AH (thirteenth century AD), who developed one of the most extreme forms of mystical philosophy in Islam based upon the doctrine of the transcendent unity of being (*wahdat al-wujud*) (Taftazani and Leaman 1996). Andalusia was also the home of the greatest expositor of Sufi metaphysics, Ibn al-'Arabi (see §6).

5 Illuminationist thought in the East

In eastern lands of the Islamic world and especially Persia, which was the main theatre for the flourishing of Islamic philosophy from the seventh century AH (thirteenth century AD) onward, primarily mystical philosophy was dominant during later centuries despite the revival of the discursive philosophy of the *mashsha'i*s, such as Ibn Sina, by Khwajah Nasir al-Din al-Tusi and others. It was in the East in the seventh and eighth centuries AH (thirteenth and fourteenth centuries AD) that the doctrines of *ishraq* with its emphasis on inner vision and illumination were revived by al-Suhrawardi's major commentators, Shams al-Din al-Shahrazuri and Qutb al-Din al-Shirazi, who was also a master of Ibn Sinan philosophy. The next three centuries saw mystical ideas and doctrines become ever more combined with the philosophical theses of the earlier schools, and figures such as Ibn Turkah Isfahani sought consciously to combine the teachings of Ibn Sina, al-Suhrawardi and Ibn al-'Arabi.

This tendency culminated in the tenth century AH (sixteenth century AD) with the establishment of the School of Isfahan by Mir Damad and the foremost metaphysician of later Islamic thought, Mulla Sadra, in whom the blending of ratiocination, inner illumination and revelation became complete (Corbin 1972). In this school the most rigorous logical discourse is combined with illumination and direct experience of ultimate reality, as seen so amply in Mulla Sadra's masterpiece *al-Asfar al-arba'ah (The Four Journeys)*. This later Islamic philosophy is certainly mystical philosophy, relying as it does on 'experiential' knowledge and direct vision of ultimate reality and the angelic worlds, a vision that is associated with the eye of the heart (*'ayn al-qalb* or*chism-i dil*). However, it is also a philosophy in which the categories of logic are themselves seen as ladders for ascent to the world of numinous reality in accordance with the Islamic perspective, in which what would be called Islamic mysticism from a Christian perspective is of a gnostic (*'irfani*) and sapiental nature, Islamic mysticism being essentially a path of knowledge of which love is the consort, rather than a way of love exclusive of knowledge.

In any case it was this type of philosophy, associated especially with the name of Mulla Sadra, that has dominated the philosophical scene in Persia during the past few centuries and produced major figures such as Hajji Mulla Hadi al-Sabzawari and Mulla 'Ali Zunuzi in the thirteenth century AH (nineteenth century AD), both of whom were philosophers as well as mystics. It is also this type of philosophy that continues to this day and has in fact been revived during the past few decades. Nearly all philosophers in Persia associated with the school of Mulla Sadra, which is also known as *al-hikmat al-muta'aliya* (literally the 'transcendent theosophy'), have been and remain at once philosophers and mystics.

In India likewise, Islamic philosophy began to spread only after al-Suhrawardi and during the past seven centuries most Islamic philosophers in that land have been also what in the West would be called mystics. It is not accidental that the school of Mulla Sadra spread rapidly after him in India and has had expositors there to this day. Perhaps the most famous of Muslim intellectual figures in India, Shah Waliullah of Delhi, exemplifies this reality (see Shah Wali Allah). He was a philosopher and Sufi as well as a theologian, and his many writings attest to the blending of philosophy and mysticism. It can in fact be said that Islamic philosophy in India is essentially mystical philosophy, despite the attention paid by the Islamic philosophers there to logic and in some cases to natural philosophy and medicine.

6 Sufism and the Akbarian tradition

No treatment of mystical philosophy in Islam would be complete without a discussion of doctrinal Sufism and Sufi metaphysics, although technically speaking in Islamic civilization a clear distinction has always been made between philosophy (*al-falsafa* or *al-hikma*) and Sufi metaphysics and gnosis (*al-ma'rifah*, *'irfan*). However, as the term 'mystical philosophy' is understood in English, it would certainly include Sufi metaphysical and cosmological doctrines which were not explicitly formulated until the sixth and seventh centuries AH (twelfth and thirteenth centuries AD) although their roots are to be found in the Qur'an and hadith and the sayings and writings of the early Sufis. The first Sufi authors who turned to an explicit formulation of Sufi metaphysical doctrines were Abu Hamid Muhammad al-Ghazali in his later esoteric treatise such as *Mishkat al-anwar (The Niche of Lights)*

and *al-Risalat al-laduniyya (Treatise on Divine Knowledge)*, and ‘Ayn al-Qudat Hamadani who followed a generation after him.

The writings of these great masters were, however, a prelude for the vast expositions of the master of Islamic gnosis Muhyi al-Din Ibn al-‘Arabi, perhaps the most influential Islamic intellectual figure of the past seven hundred years. Not only did he profoundly influence many currents of Sufism and establish an ‘Akbarian tradition’ identified with such later masters as Sadr al-Din Qunawi, ‘Abd al-Rahman Jami and, in the last century, Amir ‘Abd al-Qadir and Shaykh Ahmad al-‘Alawi. He and his school also influenced formal philosophy to such an extent that a figure such as Mulla Sadra would not be conceivable without him. The Ibn al-‘Arabian doctrines of the transcendent unity of being, the universal man, the imaginal world and eschatological realities are not only esoteric and mystical doctrines of the greatest significance in themselves for the understanding of the inner teachings of Islam, but are also sources of philosophical meditation for generations of Islamic philosophers to the present day, who have cultivated diverse and rich schools of mystical philosophy during the past eight centuries and brought into being currents of philosophical thought that are still alive in the Islamic world. One need only think of such fourteenth century AH (twentieth century AD) figures as ‘Alalamah Tabataba’i in Persia and ‘Abd al-Halim Mahmud in Egypt to realize the significance of the wedding between philosophy and mysticism in the Islamic intellectual tradition, not only over the ages, but as part of the contemporary Islamic intellectual scene (see Islamic philosophy, modern).

Mysticism, history of

Contemporary authors generally associate mysticism with a form of consciousness involving an apparent encounter or union with an ultimate order of reality, however this is understood. Mysticism in this sense, it is argued, can be found in virtually all cultures and religious traditions, and is perhaps as old as humanity itself. None the less, there is no agreement on the identifying characteristics of mystical states; the term 'mysticism' and its cognates have undergone long evolution and been used in a bewildering variety of ways.

Such ongoing disputes about the nature and significance of mysticism only underscore both the challenge and the importance of studying its history. On the one hand, without consensus on a definition, scholars disagree on which texts and figures merit inclusion in a historical survey of mysticism. On the other hand, arguments about whether mystical experiences are 'everywhere the same' can hardly be settled apart from attention to the historical evidence.

1 Methodological issues

Increasingly, scholars debate not only the data but also the proper methodology for studying mysticism's history. Lack of consensus on a definition of mysticism gives rise to corresponding disagreements over who and what to classify as truly mystical, a problem compounded by the modern tendency to identify mysticism exclusively with certain subjective experiences involving 'pure undifferentiated consciousness' or 'union'. We have no direct access, after all, to the states of consciousness of past mystics, but only to the texts and other artefacts they have left behind, from which it is generally difficult to extract clear 'phenomenological' descriptions of the sort modern commentators seek.

Another problem is that if, according to some definitions, mysticism is a fundamental mode of human consciousness present in every era, or even a tacit dimension of all human experience, a comprehensive history of mysticism would have to include all human history and experience, something obviously impossible. Still, we may suppose that for every mystic recognized today, hundreds more have left behind no traces (for example, because they lived in pre-literate communities, or their works were lost, or they felt no urge to record their experiences). Thus any account of the history of mysticism has an essentially modest scope, since it illuminates only a small portion of the totality of human mystical experience, most of which will remain forever inaccessible. At the same time, however, modern scholarship is opening up a wealth of new material that has been forgotten or under-utilized in the tradition. Feminists, for example, are retrieving the testimony of women mystics, noting what is distinctive about their experience. Such research continues to enlarge and modify our understanding of mysticism's history.

The present entry briefly traces several strands of mysticism according to the religious traditions out of which they emerged. No claim is made that this is the best or most complete approach; mystical experiences may occur to people of no formal religious affiliation. Nevertheless, even the most unorthodox of the great mystics generally have their roots in a specific religious tradition, and cannot be adequately understood apart from it.

2 Mysticism of ancient and indigenous communities

So-called 'extrovertive' or 'nature' mysticism, involving an experience of a sacred unity in and with all things, is a relatively common human phenomenon, even where evidence for other forms of mystical experience is wanting (an example here is the alleged 'mystical' quality of many prehistoric cave paintings or ancient carvings). The spiritualities of many archaic cultures and indigenous peoples involve the celebration (and sometimes restoration) of a communal and individual sense of 'oneness' with the whole created order.

Eliade (1964) and others discern a mystical element in shamanism, and in the 'spirit possession' of African mediums. Native American peoples of the Central Plains region retain the tradition of the 'vision quest', in which seekers undertake an ascetic discipline to encounter their 'spirit guide'. Though the results of these practices may not be an experience of 'undifferentiated unity', the processes involved and the ecstatic states attained bear certain affinities to the mystical disciplines of more familiar traditions.

3 Indian mysticism

Among the earliest recorded manifestations of mysticism are those from the Indian subcontinent. Even before the second millennium BC, the pre-Aryan civilization apparently practised a form of yoga. The polytheistic religion of the invading Aryans centred on ritual sacrifice, but gradually evolved in a mystical direction as its practitioners reflected upon the inner significance of the sacrifices, and Brahman (originally identified with the sacred power contained in the rites) came increasingly to be understood as a universal principle or power underlying all reality.

Out of this context, and over many centuries, emerged the Vedas, a fluid canon of sacred writings accepted as revelation (*śruti*) by orthodox Hindus; among these the Upaniṣads propose a path of mystical insight allowing liberation (*mokṣa* or *mukti*) from the vicissitudes of human existence. The Upaniṣads are concerned with the relationship between Brahman (the Supreme Soul or Absolute) and *ātman* (the eternal inner soul or self), a relationship summarized in the classic formulation *tat tvam asi*, 'thou art that'; in other words, the eternal self, realized through meditation and asceticism, is ultimately one with the Absolute (see Brahman).

The Upaniṣads themselves, however, incorporate a variety of tendencies from the preceding traditions. The Śvetāśvatara Upaniṣad, for example, contains an unusually strong theistic strain, and speaks of the path to union with the Supreme Self through devotion (*bhakti*); other Upaniṣads seem to support a strict identity between *ātman* and Brahman. The Māṇḍūkya Upaniṣad, often cited in Western philosophical discussions of mystical experience, speaks of a state of consciousness beyond dreamless sleep: 'unperceived, unrelated, incomprehensible, uninferable, unthinkable, and indescribable', 'all peace, all bliss, and nondual', 'this is *ātman*, and this has to be realized' (Māṇḍūkya Upaniṣad, 7).

Other movements emerging between 800 and 500 BC developed approaches to mysticism that were atheistic or agnostic in their implications. Like the Sāōkhya philosophy associated with classical yoga, Jainism maintains the ultimate status not of a single divine monad but of an infinity of individual souls; the goal of the mystical journey is to isolate this self-monad from its immersion in materiality. Early Buddhism, by contrast, developed the doctrine of 'no self' (*anatta*) and impermanence (*anicca*), analysing persons as a series of transitory states and denying the existence of any underlying eternal self. According to Buddhist tradition, Prince Gautama Siddhartha (born perhaps in the latter half of the sixth century BC) left home and family to seek the cause of human suffering and the way to liberation from it. After years of harsh asceticism and searching, he discovered the Middle Path (between sensuality and excessive austerity) and, while meditating beneath a *bo* (or *bodhi*) tree, attained *nirvāṇa*, that is, supreme peace and enlightenment (*bodhi*) - hence the title 'Buddha' ('Enlightened One'). The Buddha taught his disciples that by following the Noble Eightfold Path and attaining *nirvāṇa*, the cycle of rebirth, the illusion of selfhood, and the suffering caused by ignorance and craving can be overcome. In succeeding centuries, as it flourished and spread to other parts of Asia, Buddhism underwent extensive scholastic systematization (for example, in the dialectical method developed by Nāgārjuna in the second century) and evolved into several schools, most notably Theravāda (probably closer to the Buddha's original doctrine and found today in Sri Lanka, Myanmar and southeast Asia) and Mahāyāna (in China, Japan and Korea).

Crucial to the development of later Indian mysticism is the *Bhagavad Gītā*, a famous mystical poem (in the form of a dialogue between Lord Arjuna and Krishna) which presents three paths to salvation - the way of knowledge, the way of works, and the way of devotion (*bhakti*) or loving adoration - and which (on some interpretations) seems to give a higher place to *bhakti* than to contemplative yoga. Since Krishna is a manifestation of Vishnu, the poem clearly contains a theistic element, but there are monistic strains as well.

Such diverse tendencies eventually gave rise in the medieval period to three main schools of Vedānta (the 'end' or systematic explanation of the Veda) (see Vedānta). Śaōkara gave the Upanishadic formula 'thou art that' its most radical nondualistic (*advaita*) interpretation, insisting on a strict numerical identity between the soul and Brahman; though allowing for worship and devotion on the level of appearances, he believed these to be transcended in union. Against this view, the eleventh-century thinker Rāmānuja developed a position of 'qualified nondualism'; he recognized an impersonal mysticism of undifferentiated unity, but ranked it inferior to loving communion with a personal God. Two centuries later, Madhva propounded a dualistic (*dvaita*) system of thought. He argued for a radical pluralism among God (*īśvara*), individual souls and non-intelligent substances, and maintained that it is God who decides the destinies of all finite selves.

More recently, Aurobindo Ghose has attempted to combine elements of traditional Hindu theology with an evolutionary mysticism. But perhaps the best-known modern representative of Vedāntic spirituality is

Ramakrishna (1834-86), whose life and message of universalism were popularized in the West by Swami Vivekananda (1862-1902), organizer of the Ramakrishna Mission, which combined Advaita philosophy with a deep concern for social issues (see Ramakrishna Movement).

4 Mysticism in China and Japan

Despite its influence on later Hinduism, Buddhism largely died out within India itself after the revival of Vedantism. Elsewhere in Asia, however, Buddhism continued to spread and evolve as it encountered other traditions.

With its focus on harmonious relations between the 'superior individual' and a well-ordered society, early Confucianism appears as a form of ethical humanism, though a mystical element emerges more clearly in the *Book of Mencius* and in later neo-Confucianism, under Daoist influence (see Chinese philosophy §§4-5). By contrast, the *Daodejing* (ascribed to Laozi, considered the founder of Daoism) has a more mystical tone. Here the Dao or Way is regarded as both the natural order of the universe, and a life lived in harmony with that order. Laozi advises the sage to act spontaneously and effortlessly, through non-action (*wuwei*). The *Daodejing* is relatively silent on mystical disciplines or states of consciousness, which are treated in more detail in the later *Book of Zhuangzi* (see Daodejing).

Daoism exerted a powerful influence on *Chan* (Japanese *Zen*) Buddhism, a school of Mahāyāna Buddhism developed in China and Japan (see Japanese philosophy §5). Here there is a strong emphasis on sudden illumination (*satori*), often after prolonged sitting meditation (*zazen*), concentrating under the direction of a master (*roshi*) on an assigned *koan* (a paradoxical question or answer designed to stop ordinary conceptual thinking). The two principle surviving Zen schools are Rinzai and Sōtō, brought to Japan by Eisai (1141-1215) and Dōgen respectively. Dōgen and the Sōtōschool emphasize the centrality of the Zen meditation practice itself, not as a means to an end, but as the realization of one's own already present Buddha-nature. By contrast, *roshis* of the Rinzai school have traditionally used *koans* and even startling and eccentric behaviour (slaps, sudden gestures, and so on) to evoke in their pupils a condition of great doubt and mental tension leading to the sudden breakthrough of *satori*. Revitalized in the eighteenth century by Hakuin (1685-1768), who systematized the use of *koans* and left detailed descriptions of his own mystical experiences, Rinzai has become the best-known branch of Zen in the West, largely through the efforts of D.T. Suzuki (1870-1966).

5 Jewish mysticism

Though the Hebrew Scriptures describe many encounters with the God of Israel (for example, Moses before the burning bush, Elijah at Horeb, Isaiah's Temple vision), encounters often treated as paradigmatic in later Jewish and Christian mystical texts, many modern scholars prefer to classify these as numinous states, since they seem to involve the overwhelming sense of a sacred presence external to the subject, rather than an absorption into the divine. In the post-exilic period, Jewish spirituality became increasingly eschatological, even apocalyptic, giving rise in the first century BC to *merkavah* (chariot) mysticism, involving Gnostic-influenced mystical speculations on Ezekiel's vision of the throne-chariot (Ezekiel 1), and the possibility of ascending through various spheres to the divine throne. Though *merkavah* mysticism declined in the Middle Ages, it left its imprint on the more popular movement of medieval Hasidism, which through prayer and religious practices cultivated intense awareness of the omnipresent creator (see Hasidism).

The first-century philosopher Philo of Alexandria (§§1, 4), so deeply influenced by Greek thought, is usually ranked among the Hellenistic philosophers rather than within the main currents of Jewish spirituality. Nevertheless, he encourages pursuit of the direct vision of God, and develops a highly allegorical method for discerning mystical meanings in scriptural texts.

The Jewish spiritual movement known as Kabbalah found classic expression in the *Zohar* (Splendour), a massive and esoteric work claiming great antiquity but more probably dating from the thirteenth century. According to its complex speculations, echoing Gnostic and Neoplatonic themes, God is conceived as the Eyn Sof (Infinite), without qualities, but emanating ten ideal qualities, or Sefirot, the lowest of which includes the created order. Creation occurs within God, through a divinely initiated self-differentiation, and each soul contains some of the Sefirot. But since Adam's Fall, the *Shekinah*, or divine presence, has been exiled from the Eyn Sof, and so the goal

of the devout is to become aware of the divine presence within and thus help reunite the *Shekinah* with the Eyn Sof, restoring the cosmic order. Isaac Luria (1534-72), a major figure of this mystical school, conceived Adam as a cosmic figure (Adam Kadmon) whose Fall brought about the shattering of the ideal universe into the present material world, with the divine light broken up into the many sparks of individual souls; through prayer and concentrated devotion (*kevannah*) human beings could take an active role in the ultimate reintegration (*tikkun*) of all things (see Kabbalah).

More popular than speculative, modern Hasidism originated in the eighteenth century with Israel Baal Shem Tov (1700-60) and his successor Baer of Meseritz (1710-72). This mystical and devotional movement emphasizes especially the role of the Tzaddik, or perfectly righteous person, who alone can guide others effectively in their spiritual journey. Hasidism remains a strong force within contemporary Judaism.

6 Christian mysticism

Christianity rests upon Jesus of Nazareth, and his consciousness of a deep continual communion with the God of Israel, whom he boldly addresses as ‘Abba’ (‘dear Father’). This so-called ‘Abba-experience’ has been compared with the experiences of mystics, though Jesus himself (according to the evidence of the Gospels) seems to have claimed an utterly unique and unprecedented intimacy with the divine (Christian dogma identifies him as the sole incarnation of the Second Person of the Trinity) (see Incarnation and Christology §1).

Strikingly, though states arguably ‘mystical’ in the contemporary sense are reported among Jesus’ first followers, the word *mystikos* itself appears nowhere in the New Testament; on the other hand, ‘mystery’ (*mysterion*) figures prominently in the Pauline letters. Past historians of religion detected here the influence of ancient mystery cults, and claimed that Christian mysticism was largely imported. Louis Bouyer (1990) and others have argued, however, that while the secrecy of the mystery religions pertained only to their rituals, St Paul uses ‘mystery’ in a different sense, Semitic in origin, to refer to God’s hidden plan for the salvation of the world, now revealed in Christ.

None the less, Hellenistic influences on the subsequent evolution of Christian spirituality and mystical theology are undeniable, beginning with ancient Alexandria, where Plotinus (founder of Neoplatonism) and Origen (Christianity’s first great theologian) shared the same teacher, Ammonius Saccas. The views of Plotinus (§§3, 6) on the immanent presence within the intelligible and material order of the divine One from which they have emerged, and his goal of a mystical return to the One through asceticism and contemplation, struck a responsive chord with Augustine and many others. Origen (§2) was especially concerned with discovering the ‘mystical sense’ of Scripture, by which he understood the hidden presence of Christ within the biblical text. Later Christian authors of the first four centuries extended the scope of *mystikos* to Christ’s hidden presence in the sacraments, particularly the Eucharist.

With the conversion of Constantine, the early Christian ideal of martyrdom was recast in terms of austere self-sacrifice; the Desert Fathers and Mothers, as well as the major figures of the monastic movement, such as Anthony the Great (*c*.251-356), Pachomius (*c*.290-346), Basil the Great (*c*.330-79), John Cassian (*c*.360-435) and Benedict (480-543), provided guidance for a life dedicated to prayer, asceticism and the search for God.

In terms showing thorough familiarity with Neoplatonic thought, the mystical implications of God’s incomprehensibility were explored by Gregory of Nyssa (*c*.335-95), and even more thoroughly by the (apparently) late-fifth-century Syrian monk now known as Pseudo-Dionysius, so called because his writings purported to be from the Dionysius converted by Paul in Athens (Acts 17: 34). The presumed apostolic pedigree gave the Dionysian texts enormous authority throughout the Middle Ages and into modern times. In *The Mystical Theology*, this author proposes a *via negativa* or ‘apophatic’ ascent into the ‘dazzling darkness’ of the ‘superessential’ divinity by successively rejecting the applicability of all predication to it; elsewhere he outlines a corresponding *via affirmativa* or ‘kataphatic’ approach, attempting to explain in what sense God may be called perfect, good, omnipotent, and so on.

Later mystics of the Eastern Church, such as John of Damascus (*c*.674-749) and especially Simeon the New Theologian (949-1022), stressed the role of the divine Light in the divinization of the human person, restoring the divine image obscured by Adam’s Fall. Simeon in turn influenced the development of hesychasm (from *hesychia*, ‘quietness’), involving the constant repetition of the mantra-like Jesus Prayer (‘Lord Jesus Christ, Son of God,

have mercy on me, a sinner') in pursuit of the vision of divine Light. Hesychasm was successfully defended by Gregory Palamas (*c.*1296-1359), who identified the divinizing Light with the uncreated 'energies' of God.

In the vastly influential works of Augustine (§11) comes a shift towards a more psychological approach to mystical themes. Augustine traces the image of the Trinity in the faculties of the soul (intellect, memory and will), and shows interest in the differences between various types of visionary and ecstatic phenomena. The Christocentric love-mysticism of the Cistercian Bernard of Clairvaux (1090-1153) characterizes loving union with the Incarnate Word in affective rather than metaphysical terms, not as a 'union of essences' but a 'concurrence of wills', leading none the less to an experience of apparent absorption in God. Meanwhile, the mysticism of the renowned Benedictine abbess Hildegard of Bingen (1098-1179), as well as the Cistercian nuns Mechthild of Magdeburg (*c.*1210-80), Gertrude the Great (*c.*1256-1302) and Mechthild of Hackeborn (1240-98), involved numerous visionary experiences and revelatory messages. Francis of Assisi (d. 1226) and his Franciscan followers (for example, Clare of Assisi, Jacopone da Todi, Angela of Foligno, and Bonaventure) ushered in a new era of intense devotion to the humanity of Christ, with a correspondingly higher appreciation of the created order in its own right as intrinsically worthy of holy human love because the object of God's love. Mystical themes were sometimes clothed in narrative form in the popular (if often fanciful) medieval *vitae* of Christian saints. Jacobus de Voragine's *Legenda aurea (Golden Legend)*, one of the most famous books of the Middle Ages, recounts the life of the noble and learned Catherine of Alexandria, regarded as patroness of scholars and philosophers because she was allegedly martyred in the early fourth century after converting the family of Maxentius and defeating by her wise argumentation fifty philosophical opponents handpicked by the Emperor. Despite the lack of any early evidence that she ever existed, medieval accounts of her mystical marriage to Christ helped popularize her cult.

The most significant figure among Rheno-Flemish mystics of the thirteenth and fourteenth centuries is the brilliant Dominican theologian and preacher Meister Eckhart, whose more startling and paradoxical expressions in vernacular sermons brought accusations of heresy. His mystical writings are still subject to the most divergent interpretations, and parallels with Hindu and Buddhist mysticism are often noted. For Eckhart, only God truly is, since being in the strictest sense is God alone. Human creatures possess existence only 'in and through God', who is immanent in the soul's uncreated apex or ground, which is eternally one with the divine. The mystical goal is therefore to divest oneself of everything, so that God may bring the Word to birth within the soul. Eckhart likewise speaks of a Godhead beyond God, a completely unknowable and indescribable 'Ground' beyond the distinction into a Trinity of Divine Persons. Despite the official condemnations, Eckhart's influence continued in John Tauler (*c.*1300-61), Henry Suso (*c.*1295-1366), and the Friends of God movement, whose teachings were crystallized in the anonymous mystical classic, the *Theologica Germanica*.

For Jan van Ruysbroeck (John Ruusbroec, 1293-1381), the empty desert of the Godhead itself has a Trinitarian orientation, and mystics who attain union with this nameless unity are not static, but move out with the Father into the world created in the divine image. Catherine of Siena (1347-80) provides an impressive example of the apostolic force of Christian love mysticism, since her 'mystical marriage with Christ' bore fruit in a remarkable involvement with contemporary social needs, as did the mystical experiences of Catherine of Genoa (1447-1510). The fourteenth-century English mystics - among them Richard Rolle (*c.*1300-49), Walter Hilton (d. 1395), Julian of Norwich (*c.*1342-after 1413) and the author of *The Cloud of Unknowing* - offer an appealing and approachable spirituality which has found a wide audience in our own times.

The famed *Spiritual Exercises* of St Ignatius of Loyola (*c.*1491-1556) appear at first glance to have little mystical about them, but are designed to lead to a direct encounter with God. The Spanish Carmelites Teresa of Avila (1515-81) and John of the Cross (1545-91) were declared Doctors of the Church for their spiritual teaching. John is best known for his classic analysis, in *The Dark Night of the Soul* and other works, of the passive purifications endured in the search for God, though his descriptions of the joys of mystical union are even more eloquent. In various writings Teresa sought to identify, through their spiritual and psychological effects, the various stages and pitfalls in the spiritual quest; her masterpiece, *The Interior Castle*, describes the process as a journey inwards through seven progressively more interior dwelling places, leading finally to a permanent union with the Triune God already present in the soul's centre.

Francis de Sales (1567-1622), a key figure in the seventeenth-century French school of spirituality, described how a 'devout life' could be lived in any state, without requiring withdrawal from the world. Pierre de Bérulle

(1575-1629) offered a theocentric and Christocentric spirituality, directed towards conformity with the 'states' or inner dispositions of the Incarnate Word. Madame Jeanne Guyon (1648-1717) advocated quiet prayer to the exclusion of all other methods, while her disciple and director, François Fénelon (1651-1715), defended a mysticism of 'pure love' of God, free of all self-interest, even in one's own salvation; critics charged that such teachings opened the door to complete moral and religious indifferentism. Within Catholic circles, the condemnation of quietism created a distrust of mystical spirituality that persisted into the twentieth century, while evoking an interest in the suspect doctrines and authors among many Protestants.

Ironically, despite its emphasis on the experience of personal salvation, the Protestant tradition has often regarded mysticism (especially in its Roman Catholic expressions) with mistrust, as a form of 'works righteousness', or a misguided attempt to bypass the mediatorial role of Jesus. Nevertheless, Protestantism has had its own mystics, such as Jakob Boehme (1575-1624), George Fox (1624-91), William Law (1686-1761) and John Woolman (1720-72), and certain Protestant movements, such as Quakerism and pietism, have a decidedly mystical flavour.

7 Islamic mysticism

Scholars who distinguish sharply between mystical and prophetic experiences do not usually classify the prophet Muhammad as a mystic, although his experiences and certain texts in the Qur'an have lent themselves to later mystical interpretations. But Islamic mysticism seems to have first emerged on a broader scale as part of a reaction against the worldliness of the expanding Muslim empire, stressing deep personal devotion and an ascetic lifestyle in the quest for inner illumination and loving communion with God. The term 'Sufism', by which Islamic mysticism is generally known, may itself have been inspired by this lifestyle, since *suf* refers to the undyed wool worn as a sign of simplicity.

Rabi'ah (d. 801) 'is generally regarded as the person who introduced the element of selfless love into the austere teachings of the early ascetics and gave Sufism the hue of true mysticism' (Schimmel 1975: 38). Subsequent Sufi mysticism is love mysticism, and uses much of the same love imagery found in the Christian mystical tradition. The search for *marifa* (direct knowledge of God), however, sometimes led to seemingly unorthodox results. Abu Yazid (d. 875) introduced the notion of *fana*, the passing away of the empirical self, a crucial and sometimes controversial theme in later Sufi mysticism; his famous words 'Glory to me, how great is my majesty!' seemed to make a blasphemous claim to divinity. Al-Hallaj (854-922) was in fact put to death for blasphemy, after seeming to assert identity with God. Al-Ghazali (§4) was able to reconcile Sufism with orthodoxy by explaining the mystics' sense of identity with God as a kind of passing illusion brought on by the intensity of the experience.

The pantheistic Sufism of Ibn al-'Arabi (§5), though unorthodox, exerted a strong influence on the mystical poet Rumi (1207-73), who founded the Mevlevi *darwish* order, whose members engage in ritual swirling movements to induce states of intense religious devotion (the so-called 'dervish dances'). After a long decline, Sufism has enjoyed a resurgence in the West in recent years (see Mystical philosophy in Islam).

Mysticism, nature of

Mysticism continues to elude easy definition, and its nature and significance remain the subject of intense debate. The terms 'mystic', 'mystical' and 'mysticism' have been used in an astonishing variety of ways by different authors in different eras.

Nevertheless, modern philosophical discussions have tended to focus on so-called 'mystical experiences', understood as certain states or modes of awareness, allegedly found within (and even outside) virtually all faith-traditions, and variously characterized as 'consciousness without content', 'the experience of absolute oneness', 'union with the transcendent', 'immediate consciousness of the presence of God', and so on. Philosophers are particularly interested in whether such experiences constitute a 'way of knowing', and whether they provide any support for either traditional religious beliefs or unusual metaphysical claims made by certain mystics (for example, that time is illusory). Some authors argue affirmatively, on the basis of an alleged 'universal consensus among mystics', for example, or the parallels between mystical consciousness and other modes of experience accepted as cognitive. Others, however, challenge these views, noting that mystics often appear to disagree precisely along the lines of their prior religious convictions, that mystical awareness seems capable of explanation in terms of natural causes, that mystical claims (like claims about one's private feelings) do not admit of ordinary testing, or that the alleged 'ineffability' of mystical states frustrates any attempt at rational analysis.

These concerns, then, tend to shape the kinds of questions typically addressed in contemporary philosophical discussions of mysticism, such as: What is mysticism? What are the identifying characteristics of mystical experience? Is mysticism 'everywhere the same', and if so, in what sense? Are there different types of mystical experience? What is the relationship between mystical awareness and its interpretation? Are mystical experiences a 'way of knowing'? Do they involve some form of union or contact with God? Are mystical experiences 'ineffable' or 'nonlogical', and in what sense? Can drugs or other natural stimuli induce mystical experiences, and would that affect their cognitive value?

Finally, in light of the increasingly technical nature of much of the philosophical debate, in which the primary mystical sources themselves often play a relatively minor role (except as mined for brief 'proof texts'), there have been calls for renewed attention to the larger historical, cultural and religious contexts from which mysticism and mystical literature emerge, and within which they must be interpreted.

1 Background

Like 'mystery' (Greek *mysterion*), the adjective 'mystical' (Greek *mystikos*) is derived from the Greek verb *myein* ('to close', especially the eyes and lips), suggesting something secret or concealed. The term was used by Christian authors of the patristic era to refer to the 'mystical sense' of Scripture, the hidden presence of Christ in the biblical text and, by extension, in the sacraments, especially the Eucharist. Only in the late medieval and modern periods did the use of the term begin to shift to reflect a growing interest in the 'private' experiences of those alleged to have encountered the divine. The noun 'mysticism', as Michel de Certeau (1992) has shown, is itself a seventeenth-century French creation (*la mystique*), marking a turn 'away from the liturgical and scriptural context of patristic and medieval Christianity to a situation in which private illumination and unusual psychosomatic experiences became the criteria' (McGinn 1991: 312).

The academic study of mysticism developed in the late nineteenth century, with William James' classic *The Varieties of Religious Experience* (1902) offering one of the most influential early contributions to the field (which also included important works by William Ralph Inge, Friedrich von Hügel, Joseph Maréchal, Rudolf Otto, Evelyn Underhill and others). James devotes considerable attention to mysticism, offers numerous examples of mystical reports, and identifies 'four marks which, when an experience has them, may justify us in calling it mystical': ineffability, noetic quality, transiency and passivity. Of these, the 'noetic quality', or the recipient's impression that these are 'states of knowledge', is particularly important, and James argues that 'mystical states, when well developed, usually are, and have the right to be, absolutely authoritative over the individuals to whom they come', though not to those who stand outside the experience (James [1902] 1936: 414) (see James, W. §4).

Comparativist R.C. Zaehner’s famous work *Mysticism: Sacred and Profane* (1961) draws upon cross-cultural differences in the descriptions of various mystical states to support a typology of three fundamentally distinct kinds of mysticism: panenhenic (associated with ‘nature mysticism’), monistic (or ‘soul’ mysticism) and theistic (allegedly the highest form). Despite his greater familiarity with the primary texts, Zaehner’s typology has often been criticized as a form of special pleading on theism’s behalf, and for improbably lumping together, under the heading of ‘soul mysticism’, traditions with such radically divergent views on the soul as Sāōkhya-Yoga, Advaita Vedānta and Buddhist mysticism.

More influential in shaping contemporary Anglo-American philosophical discussions of mysticism has been Walter T. Stace’s *Mysticism and Philosophy* (1960a). Stace first identifies two main types of mystical consciousness: ‘extrovertive’, involving an apprehension of the oneness of all things, and ‘introvertive’, involving ‘Unitary Consciousness, from which all the multiplicity of sensuous or conceptual or other empirical content has been excluded, so that there remains only a void and empty unity’. He goes on to argue, however, that these states are related as ‘two species of one genus’, and share a ‘universal core’ of common characteristics, including ‘the apprehension of an ultimate nonsensuous unity in all things’ (though realized differently in extrovertive and introvertive states), blessedness, paradoxicality, alleged ineffability, and a sense of objectivity (Stace 1960a: 110, 131-2; 1960b: 14). Most importantly and controversially, Stace explains apparent conflicts among mystical reports from different religious traditions as the result of later interpretations superimposed on what are essentially the same experiences. He is particularly critical of Zaehner for failing to grasp the implications of the experience/interpretation distinction, and for simply concluding that Christian and Indian mysticism are different ‘from the mere fact that the *beliefs* which Christian mystics based upon their experiences are different from the *beliefs* which the Indians based on theirs’ (Stace 1960a: 35-6).

Stace’s own views on the relation between experience and interpretation have since been strongly criticized, especially by some of the authors represented in Steven Katz’s anthologies *Mysticism and Philosophical Analysis* (1978) and *Mysticism and Religious Traditions* (1983), who insist that the mystics’ religious backgrounds and prior beliefs play a much greater role in actually shaping the specific character of the experience. More recently, the contributors to Robert Forman’s collection *The Problem of Pure Consciousness* (1990) have criticized in turn this ‘constructivist’ position, defending the possibility of ‘pure consciousness events’ experientially indistinguishable across different religious traditions. Meanwhile, Peter Moore (Katz 1978), Nelson Pike (1992) and others have pointed out that many mystics themselves describe not a single mystical state, but successive degrees of mystical union, and that the ordered pattern of these distinct stages may itself have epistemic significance. At the same time, Bernard McGinn (1991) has argued that ‘presence’ is a far more useful category for the understanding of certain mystical traditions than that of ‘union’, despite the latter’s prominence in philosophical analyses (though it is not yet clear whether McGinn is simply replacing what is arguably too narrow a category with one too broad).

2 Defining mysticism

What, then, is mysticism, and what are the identifying characteristics of mystical states? Following the lead of certain mystics themselves, modern commentators often sharply distinguish mystical awareness from sensory experience, discursive thought, the ordinary reflective exercise of mental imagery and concepts, and such extraordinary phenomena as visions, voices and levitations. More controversially, some authors (for example, Ninian Smart 1965) also exclude numinous and prophetic experiences from the ‘mystical’ category, though in fact all of these experiences are hard to disentangle in the lives and testimony of actual mystics. Many would agree with James that mystical experiences seem to their recipients to be states of knowledge or insight, to possess what is variously called a ‘noetic quality’, a ‘sense of objectivity or reality’, or a ‘perception-like’ character. Most importantly, it is often claimed (though seldom in terms equally acceptable to all religious traditions) that those undergoing mystical experiences feel themselves to have attained some supreme goal, and to be in the presence of, or in union with, the Absolute, the Transcendent, the One.

However, as the brief overview in §1 suggests, a deeper philosophical consensus on mysticism’s scope and nature seems unlikely at this point, at least in part because the terminology and focus of the discussion have changed so dramatically over time, and attempts at more precise definitions now appear almost unavoidably tendentious; philosophers are naturally disinclined to count as truly ‘mystical’ anything which does not seem to fit their

particular theories. Indeed, some (for example, in Katz 1983) have argued that the whole modern preoccupation with identifying the internal features of these relatively rare and unusual states of consciousness has tended to impede a more comprehensive philosophical understanding of mysticism in all its dimensions and manifestations.

3 Mystical experience and its interpretation

Is mysticism 'everywhere the same'? This apparently simple question provokes endless philosophical debate, not only because of disagreements about the nature of mysticism, but also in part because of a lack of clarity about the kind of sameness or difference at issue. Presumably any two experiences are the same at least to the extent that they are both experiences, and different at least to the extent that they are distinguishable as two. Presumably even otherwise indistinguishable states of 'pure consciousness' or 'undifferentiated unity' may differ in intensity, duration, clarity, time of occurrence, and so on.

But what primarily interests philosophers, it seems, is whether mystical states are sufficiently alike across different periods and cultures to offer some *prima facie* support for belief in their cognitive value (or, correspondingly, to undermine any one tradition's claim to be the sole possessor of authentic mysticism). The underlying assumption here is that, other things being equal, the greater the consensus, the stronger the case in mysticism's favour (just as we tend to give greater credence to reports of unusual sightings when there is multiple attestation from independent sources). Of course, this assumption can be challenged; there are certainly cases of mass delusion. None the less, even many otherwise sceptical authors, as well as those inclined to make exclusivist claims for particular mystical traditions, have found the apparent cross-cultural similarities striking, and something that requires explanation.

Yet first impressions can deceive. As James admits, when we examine the broader field of mystical reports more closely, 'we find that the supposed unanimity largely disappears…[Mysticism] is dualistic in Sankhya, and monistic in Vedanta philosophy' ([1902] 1936: 416). Christian mystical literature speaks of union with God; Theravāda Buddhism does not. In short, mystics of different backgrounds describe their experiences in radically different ways.

To maintain the 'common core' hypothesis in the face of conflicting descriptions, authors typically distinguish the mystical experience as such from its interpretation. Ninian Smart, for example, argues that 'phenomenologically, mysticism is everywhere the same', but that 'different flavours accrue to the experiences of mystics because of their ways of life and modes of auto-interpretation' (Smart 1965: 87). Stace, as noted above, maintains that all authentic introvertive mystical states are in fact experiences of 'pure undifferentiated unity', but that 'the same mystical experience may be interpreted by a Christian in terms of Christian beliefs and by a Buddhist in terms of Buddhistic beliefs' (1960b: 10). Thus 'union with God', according to Stace, 'is not an uninterpreted description of any human being's experience', but 'a theistic interpretation of the undifferentiated unity' (Stace 1960a: 103-4).

Interestingly, Stace's approach is sometimes turned on its head in popular writings on mysticism, by authors who seem to imply that all mystics in fact experience union with God, but that some interpret this union in non-theistic terms. Most proponents of the 'common core' hypothesis, however, seem to favour 'undifferentiated unity' or 'pure consciousness without content' as the essential feature of all introvertive mystical states.

Stace in turn has been roundly criticized for his naïve approach to the experience/interpretation distinction. Peter Moore notes that, besides the 'raw experience' (that is, 'features of experience unaffected by the mystic's prior beliefs, expectations, or intentions'), the interpretive element found in mystical reports may be not only retrospective (as in Stace's view) but also reflexive ('spontaneously formulated either during the experience itself or immediately afterwards') or incorporated ('caused or conditioned by a mystic's prior beliefs, expectations and intentions') (Katz 1978: 108-9). Steven Katz goes further, insisting that 'there are NO pure (i.e., unmediated) experiences'. Rather, 'the experience itself as well as the form in which it is reported is shaped by concepts which the mystic brings' to the experience, so that Hindus have Hindu mystical experiences, Jews have quite distinct Jewish mystical experiences, and so on (Katz 1978: 26). As critics have pointed out, Katz seems to assume rather than prove the 'constructed' character of all experience, and makes his case more by way of persuasive examples than conclusive demonstration. Pressed to its limits, his radically pluralist, contextual and constructivist approach would seem to have the counterintuitive consequence of making all mystical states (and indeed all experiences) unique and incommensurable.

In response, Forman and others have argued that so-called ‘pure consciousness events’, involving ‘a wakeful though contentless (non-intentional) consciousness’, can and do occur, and that such mystical states cannot be adequately accounted for on the ‘constructivist’ model, since they contain no inner content to be ‘constructed’ in the requisite way. Moreover, in so far as such experiences occur across different traditions and cultures, they would seem to provide a clear instance of what Katz claims is impossible: a type of mystical consciousness virtually the same everywhere. Whether Forman has identified a convincing counterexample to the ‘constructivist’ position, or whether ‘pure consciousness events’ are what most classic mystical texts are actually describing, is still under debate.

Other authors, without adopting Katz’s radical pluralism, nevertheless sort out mystical states into a smaller number of basic types. Here, too, the question arises of which differences in the way such states are described correspond to important differences among the experiences themselves. Many surveys of mysticism divide their material according to the major religious traditions, although ordinarily for expository reasons alone. Zaehner, as we have seen, sharply distinguishes theistic ‘love’ mysticism from the monistic or ‘soul’ mysticism found in certain Asian religions. Neo-Thomist Jacques Maritain (1944) likewise sharply differentiates ‘supernatural mystical experience, by means of affective connaturality with the deity’, from the purely natural mysticism of Hindu yogis, involving ‘an intellectual (negative) experience of the substantial esse of the soul’. Critics charge that such distinctions are dictated as much by Maritain’s and Zaehner’s theological presuppositions as by careful attention to the mystical reports themselves. Yet while acknowledging such criticisms, Wainwright and others have defended the legitimacy in principle of a typological approach, and pointed the way towards a more sophisticated typology of mystical states.

Such ongoing disputes have spawned a vast and often highly technical literature on the relationship between experience and its interpretation, with important implications not simply for the understanding of mysticism but for epistemology in general. These discussions underscore the complexity of the hermeneutical task in interpreting mystical reports, and the necessity of focusing not just on isolated psychological states, but on the larger historical and cultural context in which they occur.

4 Mysticism and God

Although at times the ‘consensus of the mystics’ has been invoked on behalf of monism, idealism and other less well-known metaphysical doctrines, Anglo-American philosophers have tended to approach mysticism primarily in terms of what it might contribute to questions about the nature and existence of God. Authors debate whether mystical states in particular, and religious experiences in general, should be considered cognitive, and whether they provide any support for theistic belief. Most often, therefore, mysticism is discussed in conjunction with the so-called ‘argument from religious experience’, as a possible source of premises upon which one could base an inference (causal, explanatory or otherwise) to the existence of God (see Religious experience §2). Alston and others take a different approach, arguing that putative mystical perceptions of God are part of a justified belief-forming practice, in which ‘people sometimes do perceive God and thereby acquire justified beliefs about God’ (Alston 1991: 3), in much the same way that we acquire justified beliefs about external objects by directly perceiving them, and not just by an inference from internal sensory impressions.

Such an approach presumes, of course, that at least some mystical experiences have an intentional structure, and that it makes sense to talk of ‘theistic mystical experiences’. This assumption may be challenged. Forman’s ‘pure consciousness events’, for example, are characterized as ‘contentless’ and ‘non-intentional’. Stace’s states of ‘pure undifferentiated unity’ are similarly described. If one holds, with Stace, that all introvertive mystical consciousness is of this nature, then it is difficult to see how such experiences could be phenomenally ‘of’ anything. Pike has argued that even an experience of undifferentiated unity might count as ‘phenomenologically theistic’ if this ‘climax moment of the paradigm union experience is preceded by specifically theistic experience having dualistic structure’ (Pike 1992: 164). That is, just as we might correctly describe our experience of ‘stun-stars and fading consciousness’ as ‘the experience of being hit by a baseball’ if in fact we had observed the course of ball before impact, so too an undifferentiated unity might be correctly described as (apparent) union with God if it comes as the culmination of a sequence of states in which the subject-object distinction seems gradually to disappear as God and the soul draw closer.

None the less, some philosophers apparently want to claim something stronger: that the climactic experiences

described by mystics such as Ruusbroec and St Teresa are not merely states of undifferentiated unity having a ‘theistic’ phenomenological ancestry, but are themselves ‘perception-like’, involving a nonsensuous (putative) presentation of God to the mystic. The cognitive value of such experiences can then be defended by invoking some variant of what Richard Swinburne calls the ‘principle of credulity’, that ‘in the absence of special considerations what one seems to perceive is probably so’, and ‘how things seem to be is good grounds for a belief about how things are’ (Swinburne 1979: 254).

But are there in fact ‘special considerations’ that might limit the application of this principle? Antony Flew (1966), Ronald Hepburn (1967a), C.B. Martin (1959) (most famously) and others have argued that religious experiences (and thus, by implication, mystical states) do not qualify as a ‘way of knowing’ at least in part because they do not meet certain standards of testability that experiences must satisfy if they are to count as cognitive. If someone reports seeing a skunk in the basement, for example, I know how to confirm or disconfirm this (by looking, smelling, setting a trap, and so on), but ‘when someone claims to have direct awareness of God, to encounter, see, or intuit the divine, we are not able to suggest a test performance of an even remotely analogous kind’ (Hepburn 1967a: 166).

Alston (1991), Wainwright (1981) and others have responded that, in fact, religious communities use many checks and testing procedures for evaluating the authenticity of alleged mystical perceptions of God, such as: the consequences of the experience for the mystic and for others, the orthodoxy of the claims based on the experience, the similarity to paradigmatic mystical states, the judgment of qualified religious authorities, and so on. Critics reply that such tests are inadequate, especially since a sceptic can admit that a mystical state satisfies them all while denying that it constitutes an experience of God. To this, however, the usual counter-response is that standards of testability must be appropriate to the nature of what is allegedly perceived; it is not clear that different or more stringent checking procedures can reasonably be demanded for alleged perceptions of an immaterial, all-good, all-powerful personal God free to decide the occasion and recipient of divine self-manifestations.

Again, one crucial test for evaluating most perceptual claims is whether they agree with those of other qualified observers. Ordinarily, the testimony of virtually all normal observers asked to verify the same putative sensory perception (for example, of a skunk in the basement) would be more or less unanimous. By contrast, critics charge, mystics disagree even among themselves, and theistic mystical experiences seem to occur only to those who already believe in God, monistic experiences to those from monistic traditions, and so on. This suggests that mystical ‘perceptions’ of God are shaped more by the mystic’s prior beliefs and expectations than by anything independent. One possible response is to challenge the extent of the disagreements among mystics of different backgrounds, or the conformity to the recipient’s prior beliefs. Mystics seem to recognize each other across denominational boundaries, and most speak of the novelty and wonder of mystical union; in many cases, recipients have no particular religious affiliation or prior faith. The underlying issue here may be whether the actual distribution and frequency of theistic experiences across cultures is what we might antecedently anticipate if in fact God exists and is perceived in these states, or whether we would otherwise expect such experiences to be more common; philosophers argue somewhat inconclusively over God’s possible reasons for more or less self-disclosure.

Another ‘special consideration’ often mentioned is that the occurrence of mystical states seems capable of other explanations (physiological, psychological, psychoanalytical, and so on). Some authors have claimed that mystical experiences can be experimentally evoked through sensory deprivation, ‘deautomatization’ (a term coined by A.J. Diekman to describe the undoing of habitual patterns of perception by techniques such as staring steadily at an object or image; see Diekman in Woods 1980), taking hallucinogens, and so on; there is, in fact, an extensive literature on the question of drugs and mysticism. One may argue that ‘instant chemical mysticism’ is somehow too cheaply bought, and dispute whether the states thus produced actually correspond with what the mystics describe. But the mere fact that physiological and psychological processes may be involved in a mystical experience hardly discredits it, since such processes are involved in ordinary perception as well, and one can always argue that drugs simply open the doors of mystical perception rather than entirely creating the mystical experience. Of course, in most perceptual theories, putative perceptions must have the right kind of causal connection with what is allegedly perceived, but given the ‘primary causality’ traditionally attributed to God, any experience will be grounded in God’s causal activity, whatever the ‘secondary causes’ involved. To be sure, a putative mystical experience after taking drugs may be discredited, but on other grounds (for example, its bad

effects).

In short, one important line of defence of the cognitive value of mysticism, and of the practice of forming beliefs based on theistic mystical experiences, appeals to the analogy between mystical experience and other modes of experience accepted as cognitive (especially sensory experience). How plausible one finds this appeal will depend on how much significance one attaches to the various points of similarity and difference. Critics remain unconvinced, arguing that the dissimilarities outweigh the similarities.

5 Other questions

Mystics' comments about the strangeness of their experiences or their difficulties in describing them have sometimes provoked elaborate philosophical analyses of the 'ineffability' and 'paradoxicality' of mystical states. Yet few mystics actually claim that their experiences are radically 'ineffable' or 'paradoxical' in the self-defeating sense so easily refuted in philosophical discussions. Perhaps these discussions are most useful as reminders of the complex and creative use of language in mystical literature: sometimes descriptive, sometimes prescriptive, often evocative (the frequent recourse to poetry and symbolism is notable).

Again, while some authors assert that mystics experience union with the Supreme Good and the source of all morality, others claim that mystics pass beyond all oppositions, including the distinction between good and evil. Not surprisingly, therefore, philosophers have shown some interest in the relationship between mysticism and ethics.

Certain neo-scholastics (Jacques Maritain, Réginald Garrigou-Lagrange) and 'transcendental Thomists' (Karl Rahner, Bernard Lonergan), as well as authors from other traditions (process thought, for example), have developed their own distinctive approaches to the understanding of mysticism, relatively neglected by contemporary analytic philosophers perhaps because couched in unfamiliar categories and terminology. More generally, the 'turn to the subject' in modern theology and efforts (since Schleiermacher) to ground theological claims in religious experience raise important philosophical issues as well. A particularly delicate question is to determine how mystical and religious experience might provide more than mere reinforcement of what is already believed, without adding to or subtracting from the original revelation.

Finally, despite analytic philosophy's tendency to focus on mystical states of awareness, it should not be thought that this is all mysticism has to offer philosophy. Historically, philosophers have often been influenced by their reading of mystics (for example, Schelling by Boehme, Schopenhauer by the Upaniṣads, Heidegger by Eckhart) in much more complex ways. Mysticism, understood broadly, may have contributions to make in many areas, such as the philosophical understanding of the self and personal identity, for example, or aesthetic theory. Most importantly, contemporary philosophers need to recall that, for all their interest in the internal characteristics of mystical consciousness, they generally have no direct access to mystical states, but only to mystical texts, composed in a particular genre, for a particular audience, in a particular cultural and historical setting, and so on. Without greater attention to the special hermeneutics of mystical texts, contemporary philosophers will continue to run the risk of analysing with ever greater sophistication a 'mysticism' that exists nowhere in reality, and seems far removed from the actual experience and testimony of actual mystics.

Næss, Arne (1912-)

As professor of philosophy in Oslo between 1939 and 1970, Arne Næss contributed to a strengthening of the position of philosophy in Norwegian academic life. During the German occupation (1940-5) he played an active part in the resistance movement. In the 1940s and 1950s he was the inspiration for and centre of a group of students of philosophy and social science, the 'Oslo School', whose members became influential in the later development of these fields. His philosophical thinking passed through an early 'scientistic' period of radical empiricism to 'possibilist' and pluralist views, and an undogmatic scepticism. After resigning his professorship in 1970, he became the protagonist of a version of ecological philosophy, 'deep ecology'. He has always been an admirer of Spinoza and has also sought inspiration in Spinozism for his ecological philosophy.

Although the Norwegian philosopher Arne Næss had contact with the Vienna Circle of logical positivists in 1934-6, his early views were more influenced by pragmatism than by positivism (see Logical positivism; Pragmatism). He did not accept that empirical methods have no place in philosophy, and he had reservations about the logical positivists' use of a priori formal-logical methods. But he shared their high esteem of science and the idea of making philosophy more scientific, and he supported the international movement for unified science.

In his first major work, *Erkenntnis und wissenschaftliches Verhalten* (Cognition and Scientific Behaviour, written in Vienna 1934-5), Næss sketched a programme for an empirical science of science, attacking 'subjective models' in traditional accounts of cognition and research. During his first years as professor of philosophy in Oslo he developed a programme of empirically based foundation research involving criticism of unclear use of language. He provided the groundwork for a scientific semantics by introducing a conceptual framework which made semantic hypotheses testable by empirical investigations of actual usage. Næss' empirical semantics became a common methodological basis for a circle of students from different fields who attached themselves to his programme of foundation research - the 'Oslo School'. In this milieu, key formulations in the history of philosophical ideas were regarded not as expressions of definite doctrines but as highly ambiguous formulations which might be interpreted in an indefinite number of directions, and which could be made more precise.

Næss was inclined to consider the difference between normative and descriptive statements as one of degree rather than a clear dichotomy. He rejected the view that moral philosophy must be meta-ethics, a science *about* norms and their function and not a doctrine *in* morals. He envisaged a value-theoretical foundation research that sought justifications for norms, compared norm systems and sharpened normative formulations. Such a view was the basis for his later investigations of norm systems such as Gandhi's ethics of non-violence (see Gandhi, M.K.).

Næss employed concepts and methods of empirical semantics on politically controversial subjects, in several investigations of uses of the term 'democracy', for example, in studies supported by UNESCO (see Democracy); he also undertook empirical studies of philosophically relevant terms.

In the early 1950s Næss moved away from the semantically and empirically oriented platform of the Oslo School. He continued his Spinoza studies, but also started work on a comprehensive history of philosophy, making extensive use of his semantic methods on philosophical texts. He also began to reflect critically on empiricism as a fundamental position. In a series of lectures in 1953 (see Næss 1959) he discussed the presuppositions of empiricism, and considered standpoints resulting from negating or abolishing one or more such premises (see Empiricism). He sketched a series of different views, from 'narrow scientism' via 'empiricism without dogmas' and 'probabilism' to extremely wide 'possibilism'. His work in the history of philosophy changed his conception of philosophy, and inspired him to a pluralistic doctrine of philosophical systems and 'total views', which was connected with his possibilism. He espoused a thesis of 'incommensurability' of total systems (see Incommensurability).

In *Scepticism* (1968) Næss discussed Pyrrhonism, which he considered the most radical and important form of scepticism, taking his point of departure from Sextus Empiricus (see Pyrrhonism). Næss' own position was a kind of spectator standpoint, he was a 'sympathetic metasceptic' trying to present the sceptic in as favourable and coherent a light as possible. But the sceptical attitude obviously appealed to Næss and was in harmony with deep tendencies in himself: the need for distanced, theoretical non-attachment, except in questions in which he was

emotionally strongly engaged.

A tension between engagement and distance seems to mark his development. After theoretical work in philosophy of science in the 1930s, Næss played an active part in the resistance movement during the war, at considerable personal risk. After technical work in empirical semantics, logic and the philosophy of language, studies of Spinoza and the history of philosophy, and investigations of norm systems in the 1950s and 1960s, he became strongly interested in ecological philosophy from about 1970. He took part in nonviolent action for the preservation of nature, and he became known among environmentalists all over the world as a protagonist of 'deep ecology'.

In his famous 1973 paper, 'The Shallow and the Deep, Long-Range Ecology Movement', Næss distinguished between a shallow and a more 'revolutionary' deep ecology movement. The purpose of the former is to fight against pollution and resource depletion; its central objective is to promote the health and affluence of people in the developed countries. In contrast, the deep ecology movement rejects the distinction between humans and environment, emphasizing their intrinsic relationship and total-field image. Further, the deep ecology movement stresses biospherical egalitarianism in principle, promoting a deep-seated respect for ways and forms of life; it emphasizes principles of diversity and symbiosis, repudiates class differences, favours complexity over complication, local autonomy and decentralization against centralization - and fights against pollution and resource depletion, but without losing sight of the other points. In the theoretical foundation for deep ecology, Næss integrates elements of his earlier philosophical achievements and adds new points. In 'The World of Concrete Contents' (1985) he suggests that the difference between environment conservers and developers is one of ontology rather than ethics. Clarification of differences in ontology may contribute significantly to the clarification of different policies and their ethical basis. As an ontological basis for deep ecology, Næss explores a kind of neutral monism identifying the world (reality) with the set of 'concrete contents' in the form of Gestalts, as against abstract structures such as those developed in scientific theories. This 'Gestalt ontology' is contrasted with an ontology distinguishing things in themselves with 'objective' primary qualities and relations from 'subjective' secondary and tertiary qualities (see Primary-secondary distinction). *In* the concrete contents there are no subject-object, primary-secondary or fact-value distinctions (see Fact-value distinction).

Nāgārjuna (*c.* AD 150-200)

Nāgārjuna was the first Buddhist philosopher to articulate and seek to defend the claim that all things are empty, that is, devoid of their own essential nature. A native of South India, as the founder of the Madhyamaka school of Mahāyāna Buddhism he exerted a profound influence on the further development of Buddhist thought in South and East Asia. When he claimed that all things are empty, he denied that anything exists solely in virtue of its own inherent nature. If, as all Buddhists hold, existents only arise in dependence on other existents, then nothing may be said to have a determinate nature apart from its relations to other things. Yet prior developments in Buddhist philosophy had presumably shown that anything lacking an independent nature is a conceptual fiction and not ultimately real. Thus if all things are empty, nothing is ultimately real. Still Nāgārjuna claimed not to be a nihilist. Emptiness is rather the defeat of all metaphysical theories, all attempts at grasping the ultimate nature of reality - including nihilism. Insight into emptiness is said to free us from our tendency conceptually to construct an ultimate truth, a tendency that bolsters our sense of self. Thus realization of emptiness is, Nāgārjuna held, required in order to attain full liberation from the suffering caused by clinging.

1 Historical context

Nāgārjuna was the first philosopher systematically to develop the assertion made in the *Prajñāpāramitā* (Perfection of Wisdom) literature of early Mahāyāna Buddhism that all things are empty (*śūnya*). His principal work, *Mūlamadhyamakakārikā(Fundamental Treatise on the Middle Path)* serves as the foundational text of Madhyamaka, one of the two chief philosophical schools of Mahāyāna. Another surviving text, *Vigrahavyāvartanī(Refuting the Opponents)*, replies to various objections to the doctrine of emptiness. Modern scholars are divided over the authorship of several other works traditionally attributed to Nāgārjuna.

Nāgārjuna's claim that all things are empty, that is, devoid of 'own essential nature' (*svabhāva*), is in part a response to earlier developments in Buddhist philosophy. Early Buddhists held a reductionist view of persons, according to which the continued existence of a person just consists in the occurrence of a causal continuum of impersonal, impermanent, physical and psychological elements. In the Abhidharma or scholastic phase of Buddhism, this reductionist tendency was developed into a thoroughgoing denial of all partite entities as mere conceptual fictions, things that are commonly thought to exist only because of our use of such convenient designations as 'forest', 'chariot', and 'person'. Yet our use of such convenient designations does have utility, and this fact requires explanation. Thus it was thought that while the chariot is ultimately unreal, there must be some set of ultimately real impartite entities, the behaviour of which explains our use of 'chariot'. Such an ultimately real entity is a *dharma*, defined as that which bears its own essential nature. This definition was arrived at by way of the fact that the essential properties of a complex entity are all borrowed from its parts: that a chariot serves as a mode of transportation is to be explained in terms of facts about its parts and their relations. Since such explanation must terminate in entities that are ultimately real, these must be conceived of as bearing their own essential nature. Thus when Nāgārjuna states that all things are empty, he is denying that there are any ultimately real entities.

2 Arguments for emptiness

Nāgārjuna's basic strategy in arguing for the emptiness of all existents is to seek to show that the assumption that real entities bear their own essential nature leads to absurdities: implications that either contradict the official position of some Abhidharma theory, or else fly in the face of common sense. The argument of *Mūlamadhyamakakārikā* 3 is an instance of the first sort of *reductio*. It was a received view among Ābhidharmikas that there are six sense faculties (the sixth being a kind of inner sense), each with its own distinct class of sense-object (see Buddhism, Ābhidharmika schools of §§3-4). Since consciousness was claimed to arise in dependence on contact between sense-faculty and sense-object, this doctrine could be used to demonstrate the radical impermanence of consciousness (and thus to support the view that there is no self). But Nāgārjuna points out that if, for example, the faculty of vision is thought to be a *dharma*, then it must bear its own essential nature of seeing. Yet vision cannot see itself, as no (impartite) entity may operate on itself. Vision manifests its essential nature of seeing only in the presence of a visible sense-object and light. Thus vision may not be said to bear its own essential nature of seeing; rather, it borrows its essential nature from the conditions on which seeing depends.

Vision is not, then, an ultimately real entity, but merely a conceptual fiction. And if consciousness does arise, it can only do so in dependence on causes and conditions that are themselves ultimately real. Thus the Ābhidharmika may not claim that consciousness arises in dependence on vision, or any of the other sense faculties either.

The view that ultimately real existents bear their own essential nature also contradicts common sense, for example, the fact that existing things undergo alteration. For if all existents are indeed impermanent, then alteration must ultimately require that things lose their essential nature, which is incoherent. If being young is the essential nature of the youth, and being old the essential nature of the aged, who is it that undergoes ageing (*Mūlamadhyamakakārikā* 13.5)? Indeed, it would appear that if what makes an entity ultimately real is that it bears its own essential nature, then the ultimately real could never be created or destroyed. For creation involves the acquisition of essential nature from the causes and conditions responsible for creation, which would make essential nature ‘borrowed’ and not ‘its own’. And since destruction involves loss of essential nature, there can be no ultimately real subject of destruction.

An additional though related problem with the notion of a *dharma* concerns the relation between essential nature and the bearer or substrate of essential nature (*Mūlamadhyamakakārikā* 5). If it is the function of essential nature to characterize the bearer, then presumably the bearer must itself be an existent. But if the bearer is itself of some determinate nature, then the function of essential nature becomes redundant. Yet it seems incoherent to suppose that the bearer is in itself utterly devoid of any nature; we only seem able to imagine such a thing because we tacitly supply the bearer with the nature of being devoid of determinate nature. Finally, it would be wrong to suppose that a *dharma* consists only of essential nature without underlying bearer, since then we should be unable to distinguish between distinct instances of a given *dharma*.

Through arguments such as these, Nāgārjuna seeks to show that all things are empty, that is, that it is not the case that there are ultimately real entities. This is not, however, nihilism, for neither is it the case that ultimately there is nonexistence. Nāgārjuna claims that in order to grasp the concept of the nonexistent, we must understand the notion of the existent. What we have presumably discovered through the investigation of the concept of a *dharma* is that the notion of the ultimately existent is incoherent. It follows, then, that we cannot give coherent content to the nihilist’s claim that reality is ultimately devoid of existents. To say that all things are empty is not to propound a metaphysical thesis, is not to seek to characterize the ultimate nature of reality, but rather to reject the very idea. Nāgārjuna calls those for whom emptiness is itself a metaphysical thesis ‘incurable’ (*Mūlamadhyamakakārikā* 13.8). Emptiness is not itself a property of ultimately real things; emptiness is just a conceptual fiction, it too is empty.

To this it was objected (*Vigrahavyāvartanī* 5-6) that Nāgārjuna cannot consistently seek to demonstrate that all things are empty, since such demonstration would require that there ultimately exist valid means of knowledge, as well as objects on which these means or instruments operate. Any ‘proof’ of emptiness would then be fallacious, in that it would presuppose the existence of ultimately real entities. To this objection Nāgārjuna replies (*Vigrahavyāvartanī* 30-51) by first denying that he seeks to prove a thesis. He then argues that there can ultimately be no such things as valid means of knowledge: any attempt to demonstrate that a given procedure is a means of knowledge will either be a mere dogmatic assertion, or else be subject to either circularity or infinite regress. Thus all supposed means of knowledge are likewise empty: none has the nature of a valid means of knowledge independently of other existents.

3 Interpretations of Nāgārjuna

Nāgārjuna’s response to the above objection, to the effect that his position is self-stultifying, is ambiguous. He might be taken as claiming that it is futile to assert any thesis concerning the ultimate nature of reality because its true nature is only obscured through such conceptual constructions as the so-called means of knowledge. In this case he does recognize such a thing as the ultimate nature of reality, though perhaps as apprehended only through some non-discursive means such as mystical intuition. Alternatively, he might be understood as a kind of global anti-realist, claiming that since a cognitive procedure could count as a valid means of knowledge only in the context of certain concrete human institutions and practices, the very idea of ‘the ultimate nature of reality’ is incoherent, since it requires that we be able to give content to the notion of how things are independently of any human institutions and practices.

Nāgārjuna's claim that emptiness is itself empty results in a paradox: the ultimate truth is that there is no ultimate truth. This and related paradoxes came to play a central role in Mahāyāna Buddhist practice. The two different ways of understanding Nāgārjuna are reflected in two different ways of understanding such paradoxes. One way is to see them as pointing beyond our conventional discursive practices to a reality that cannot be grasped conceptually. But on the global anti-realist reading, such paradoxes are instead meant to force us to abandon the quest for ultimate truth by getting us to see the very idea of ultimate truth as the final obstacle to attaining enlightenment. On this interpretation, the ultimate truth is that there is only conventional truth, a set of discursive practices that originate in dependence on contingent human needs and interests.

Nāgārjuna suggests the first interpretation when he speaks of ultimate reality as 'at peace, not populated with conceptual fictions, devoid of construction, not having many meanings' (*Mūlamadhyamakakārikā* 18.9). But it is the second interpretation that is supported when he goes on to equate such soteriologically privileged terms as *nirvāṇa*, the Buddha and liberation with the ostensibly opposed mundane concepts of, respectively, cyclic rebirth, the unenlightened and bondage. These equations - made on the grounds that both members of each pair are equally empty - suggest that enlightenment through realization of emptiness should not be construed as insight into a reality somehow purified of all conceptual contamination. To realize emptiness is just to see that our practices do not require grounding in things that bear their own essential nature.

One final piece of evidence derives from the frequency with which Nāgārjuna appears to violate either non-contradiction or excluded middle, as in his claim that an existing substance such as earth or space is not existent, not nonexistent, not both, and not neither (*Mūlamadhyamakakārikā* V.6-7). This sort of statement has sometimes been taken to show that Nāgārjuna rejects logic altogether in his account of reality. The Buddha, however, used a similar locution to emphasize the point that the subject of some predication fails to refer: just as we would not ask concerning a fire that has gone out in what direction it has gone, so we cannot say of, for example, the enlightened person that they are reborn, not reborn, both, or neither - since ultimately there are no persons. Thus those who favour reading Nāgārjuna as a global anti-realist would claim that when he says reals neither arise nor fail to arise nor both nor neither, he is best seen as simply denying that coherent sense can be made of the notion of how things ultimately are.

Nagel, Ernest (1901-85)

Ernest Nagel was arguably the pre-eminent American philosopher of science from the mid 1930s to the 1960s. He taught at Columbia University for virtually his entire career. Although he shared with Bertrand Russell and with members of the Vienna Circle a respect for and sensitivity to developments in mathematics and the natural sciences, he endorsed a strand in the thought of Charles S. Peirce and John Dewey that Nagel himself called 'contextual naturalism'. Among the main features of contextual naturalism is its distrust of reductionist claims that are not the outcomes of scientific inquiries.

Nagel's contextual naturalism infused his influential, detailed and informed essays on probability, explanation in the natural and social sciences, measurement, history of mathematics, and the philosophy of law. It is reflected, for example, in his trenchant critiques of Russell's reconstruction of the external world and Russell's epistemology as well as cognate views endorsed at one time or another by members of the Vienna Circle.

1 Life

Ernest Nagel was born on 16 November 1901 in Novomesto, Slovakia. He came to New York City in 1911. Educated in the New York City school system, he received a BS degree from The College of the City of New York in 1923. While teaching mathematics in the New York City public schools, he received an MA from Columbia University in 1925 and a Ph.D. in 1931 for a dissertation on the logic of measurement. After spending one year as an instructor at The College of the City of New York in 1930-1, he moved to Columbia University in 1931. He became a full professor in 1945, was appointed to the John Dewey professorship in 1955 and to a University professorship from 1967 until he retired in 1970. He served as an editor of *The Journal of Philosophy*, *Philosophy of Science* and *The Journal of Symbolic Logic*. He died on 20 September 1985.

2 Philosophy of science

According to Nagel, science, understood as an 'institutionalized art of inquiry' has contributed to the articulation and realization of 'aspirations generally associated with the idea of a liberal civilization' (1961: vii). As a consequence, the relatively recent identification of philosophy of science as a special branch of study should not let us forget that topics covered under this rubric 'are continuous with those that have been pursued … for centuries under such traditional divisions of philosophy as "logic", "theory of knowledge", "metaphysics" and "moral and social philosophy"'. Nagel wrote interestingly on all of these subjects; but his most extensive and best-known contributions are focused on topics in what he called 'the logic of science'. As with the later Peirce and with Dewey, Nagel understood logic to cover methodological issues as well as formal syntactic and semantic questions. He thought the logic of science could be divided conveniently into three parts: (a) the nature of scientific explanations, including not only their formal characterization but also the relations of the different types of explanation to one another, their functions in inquiry and how they contribute to systematizing knowledge; (b) the structure of scientific concepts, including their linkages to observational data, conditions of meaningfulness and explication via methods of definition and measurement; (c) evaluation of claims to knowledge, including the structure of probable inference, criteria for weighing evidence and the validation of inductive arguments. Nagel's best-known and most extensive publications have focused on topics related to explanation, probability and probable reasoning, but his many articles cover aspects of all three parts of this classification (see Scientific method).

3 Observation and theory

In 'Verifiability, Truth and Verification' of 1934 (Nagel 1956: ch. 7) and his critique of Russell's phenomenalism in the 1940s, Nagel insisted that the reports articulating the observed results of experiment and controlled observation used in scientific inquiry assume background information. In this sense, they are 'theory laden'. However, in*The Structure of Science* (1961) and in his comments on M. Hesse and P. Feyerabend in the late 1960s and early 1970s, Nagel denied that understanding reports of outcomes of tests of a hypothesis need or should ever presuppose the hypothesis under test. Laws that are explained by a given theory are experimental in that context when their terms may be interpreted observationally and can be confirmed or disconfirmed without presupposing the theory. Universal generalizations within a theory that cannot meet these context-relativized requirements for

being experimental utilize concepts whose 'structural' features are characterized by the basic principles of the theory (that Nagel thought could be formally presented as a 'calculus' at least in principle). How such structural features are characterized is first elaborated in two papers Nagel wrote in the 1930s, on the emergence of the notion of pure geometry as distinct from a theory of spatial relations and pure mathematics as distinct from a science of quantity. Nagel sought to bypass the conflict between his two teachers, the realist M.R. Cohen and the instrumentalist J. Dewey, by arguing that realist and instrumentalist understandings of scientific theories and theoretical entities do not reflect a substantive disagreement (see Scientific realism and antirealism; Observation; Laws, natural).

4 Explanation

Nagel claimed that the 'distinctive aim' of scientific inquiry is 'to provide systematic and responsibly supported explanations'. Because explanation is a distinctive aim of inquiry, Nagel recognized that a clarification of the common features of scientific explanations is also a clarification of common features of the aims of scientific inquiries. Consequently, an account of scientific explanation is inevitably going to require an examination of pragmatic aspects of scientific explanation. For example, Nagel insisted that deductive explanations of laws require that the law to be explained be less general than the explaining laws in a manner that required reference to the intended domains of application of the laws whose levels of generality are being compared.

In addition to deductive explanation, Nagel wrote on probabilistic, functional and statistical explanation. According to his classic discussion of goal-directed systems and functional explanation in biology and the social sciences, the claim that a system *S* is goal directed with respect to goal *G* is explained by showing it to be a logical consequence of a set of explanatory premises including causal laws that show how goal state *G* is realized relative to a variety of antecedent conditions. Ascribing a function *F* to the system *S* presupposes that *S* is goal directed to some goal and that *F* contributes to the realization of that goal. Nagel applied his account of functional explanation both to biology and to anthropology and sociology where he undertook a critical examination of the notions of functional explanation promoted by Malinowski and Radcliffe-Browne (see Functionalism in social science).

Nagel's relativization of the deterministic or nondeterministic character of theories to how states of systems characterized by such theories and their laws are specified allowed him to claim that theories such as classical statistical mechanics may be viewed as deterministic when the states of aggregates are represented statistically and as indeterministic when the states are represented as mechanical states (see Determinism and indeterminism). The contextual naturalism infusing his informed discussion of reduction of one theory to another is manifested by the remark: 'if and when the detailed physical, chemical and physiological conditions for the occurrence of headaches are ascertained, headaches will not thereby be shown to be illusory' (1961: 366) (see Explanation; Reduction, problems of).

5 Probability, confirmation and induction

Nagel's classic monograph *Principles of the Theory of Probability* (1939) is a philosophical survey of issues pertaining to applications of the calculus of probability as these issues were seen in the 1940s and 1950s. Nagel tended to favour the limit of relative frequency interpretation of Venn and Von Mises as a way of understanding applications of the calculus of probability within scientific theories. Although he was sympathetic to efforts to clarify conceptions of weight of evidence and evidential support, he was a trenchant critic of the efforts of Keynes, Carnap and Reichenbach to use various interpretations of the calculus of probability to develop notions of degree of confirmation and evidential support. In this connection, the methodological parts of Nagel's collaboration with M.R. Cohen, *An Introduction to Logic and Scientific Method*, should also be mentioned (see Probability, interpretations of).

6 Other topics

Nagel wrote extensively on the methodology of the social sciences as well as the natural sciences. He was concerned to defend the autonomy of the aims of scientific inquiry from those who insisted that science was laden with moral, political or social agenda. He was a sceptical critic of psychoanalytic theory, and had interesting things to say about philosophy of law.

Nagel shared with many members of the Vienna Circle the notion that extending the methods of inquiry used in

the natural and social sciences to social and political problems would promote an approach to such problems free of the totalitarian tendencies so prevalent in Europe during much of his career. However, his association with the logical empiricists did not reflect a sympathy with the their positivist tendencies. He was, as he put it, a contextualist naturalist throughout.

Nagel, Thomas (1937-)

The comprehensiveness of Thomas Nagel's approach to philosophy sets him apart among late-twentieth-century analytic philosophers. Nagel develops a compelling analysis of the fundamental philosophical problems, showing how they result from our capacity to take up increasingly objective viewpoints that detach us from our individual subjective viewpoints as well as from the viewpoints of our community, nation and species. Our essentially dual nature, which allows us to occupy objective as well as subjective viewpoints, poses unsolvable problems for us because subjective and objective viewpoints reveal conflicting facts and values. Our ability to undertake increasingly detached viewpoints from which objective facts come into view indicates that we are contained in a world that transcends our minds; similarly, our ability to examine our values and reasons from a detached or impartial objective viewpoint implies that moral values are real in the sense that they transcend our personal motives and inclinations. Yet Nagel also holds that our capacity for objective thought is limited by the fact that we cannot detach ourselves completely from our own natures in our attempts either to know our world or to act morally. Subjective facts are equally a part of reality and our moral outlook is essentially the outlook of individual agents with personal and communal ties. Consequently, Nagel argues against any form of reductionism which holds that only objective facts and values are real or which attempts to explain subjective facts and values in terms of objective ones.

1 Life

Thomas Nagel was born in 1937 in Belgrade, Yugoslavia, becoming a naturalized US citizen in 1944. He was educated at Cornell University, Oxford University and Harvard University. His career began at the University of California, Berkeley, where he spent three years before moving to Princeton University in 1966 and then to New York University in 1980.

Nagel stands out among his contemporaries for the breadth of his work, which encompasses metaphysics, epistemology and moral philosophy, and for his development of a comprehensive realistic approach. He is also distinguished by the nontechnical nature of his argumentation, which is accessible to non-professionals.

2 Metaphysics

Nagel's realism is complex in that it advances one intuitive idea at the core of the realist outlook, the idea of a world that contains and radically transcends us, at the cost of the intuitive and equally core idea of a single objective reality. For Nagel, the 'pure idea of realism' is the idea 'that there is a world in which we are contained' (1986: 70). He understands the idea of containment in terms of mind-independence. Thus, the world is independent of us not only causally, but also epistemically: the way things are might completely transcend our ability to know them, even to think about them. His development of this idea in terms of the distinction between subjective and objective standpoints entails that there is no single way that things are in themselves. If, as Nagel holds, reality includes all the myriad subjective viewpoints and the subjective facts they make available, then there is no one way that things are. It is not possible to give a single account from the completely detached or objective view, because such an account would fail to include subjective facts (that are only available from irreducibly distinctive subjective viewpoints).

Hence Nagel's approach is not only anti-verificationist and anti-idealist in its commitment to the intuitive idea of a mind-independent world. His realism is also anti-reductionist, because of its denial of the idea of a single objective reality. As both reductionism and idealism are prevailing tendencies in contemporary philosophy, Nagel's views on many issues challenge the prevailing positions. On the one hand, Nagel objects that many contemporary approaches, such as that of the later Wittgenstein, are essentially idealist in that they involve 'a broadly epistemological test of reality'. On the other hand, as we will see, Nagel opposes a variety of reductionist accounts by arguing that the phenomena at issue are subjective facts or values that cannot be described or explained from a more objective standpoint in terms of objective facts or values. Nagel's anti-reductionist arguments thus depend on whether he is right that the recalcitrant phenomena are essentially subjective (see Realism and antirealism).

3 Theory of knowledge

Nagel's realist construal of the distinction between subjective and objective viewpoints affirms a traditional

understanding of the problem posed for theories of knowledge that does not allow for revisionist resolution. The problem, according to Nagel, is that while knowledge needs to be objective and so requires that we undertake increasingly objective standpoints, we can only do so to a limited extent, since any outlook that we can occupy will be to some extent subjectively bounded.

Since we cannot attain the completely detached viewpoint from which we could examine our own attempts at understanding the world, Nagel affirms the possibility of sceptical doubt, opposing the anti-sceptical trend which holds that sceptical worries are unwarranted or even incoherent because they impose a theoretical demand for justification of our system of beliefs as a whole from an unobtainable, completely objective standpoint. Moreover, since Nagel urges that knowledge should be of what is correct, even if it is inaccessible to us, he opposes reductive theories which attempt to meet scepticism by reducing the aim or scope of knowledge to concern the way the world appears from the limited objective viewpoints that we can undertake rather than the way it really is. Though he believes that the possibility of limited objectivity is associated with the possibility of scepticism, Nagel endorses a heroic approach to knowledge, like that of Descartes, which acknowledges that we cannot detach from our perceptual and cognitive faculties completely, but attempts to use a priori argumentation to form a conception of our situation as knowers none the less (see Descartes, R. §3; Scepticism).

4 Theory of mind

Commitment to the irreducibility of subjective facts leads Nagel to argue that the mind-body problem could only be solved, if at all, by a complete and as yet unimaginable revision of our conception of the basic constituents of the universe. Nagel explains that the relation of the mind and the body seems problematic if, as a result of the success of physical science, one holds a physical conception of objective reality, and espouses a reductionist programme according to which all phenomena must be explainable reductively in terms of physical objective facts. In opposition, he argues that the qualitative nature of conscious experience is a subjective feature of reality available only from a first-person subjective viewpoint. Hence, though the qualitative aspects of conscious experiences are part of reality, they cannot be explained in terms of objective facts in general or physical objective facts in particular.

The precise force of Nagel's denial of the possibility of psychophysical reduction is important. He is not denying that we are physiological organisms or that the central nervous system (in vertebrates) and its physical states is necessary for subjective mental states. He is not denying that conscious organisms are made up of the same ultimate constituents that constitute all the physical phenomena in the universe. Rather, Nagel is proposing that our conception of the ultimate constituents as physical is too narrow for explaining that some combinations of those constituents have conscious experience. He is arguing for a dual-aspect approach, according to which the ultimate constituents are dual in nature - both physical and mental- in the sense that they can be combined to form physical things which have physical properties and conscious organisms which have the subjective properties of conscious experience (see Consciousness §2; Qualia).

5 Moral philosophy

Nagel uses the distinction between subjective and objective viewpoints to articulate a non-metaphysical understanding of moral realism, to explain the bifurcation in moral philosophy between consequentialist and deontological approaches and to argue against consequentialism, even while showing that the tension between more and less impartial moral outlooks often cannot be reconciled (see Consequentialism; Deontological ethics). Nagel's discussion of these issues illuminates the differences between the role of the objective standpoint in moral as opposed to factual or empirical thought.

According to Nagel, 'the view that values are real is not the view that they are real occult entities or properties, but that they are real values: that our claims about value and about what people have reason to do may be true or false independently of our beliefs and inclinations' (1986: 144). To be ethical is to examine one's reasons for acting from more than one's own particular perspective. Hence, unlike factual understanding, moral understanding 'is not a question of bringing the mind into correspondence with an external reality which acts causally on it, but of reordering the mind itself in accordance with the demands of its own external view of itself' (1986: 148). Consequently, while the truth about the empirical world may completely transcend our theoretical reason, the truth about how we should act could not completely transcend our practical reason. Hence, unlike metaphysical versions

of moral realism, Nagel's normative realism is not associated with the possibility of moral scepticism according to which the objective viewpoint shows that there are no values, only facts about people's inclinations and motives.

Since consequentialism has been understood as advocating an impartial point of view, that of an impartial spectator, Nagel's discussion of moral theory in terms of the possibility of undertaking an impartial or objective viewpoint is not entirely new. However, Nagel gives a more complete and nuanced treatment of both deontological and consequentialist approaches by distinguishing between agent-relative and agent-neutral reasons in terms of two correlative distinctions that are also generated by our dual viewpoints: the distinction between what we do and what happens and between choosing actions as opposed to choosing states of the world. Reasons that are relative to the agent are 'specified by universal principles which nevertheless refer ineliminably to features or circumstances of the agent for whom they are reasons'. Reasons that are neutral with respect to the agent 'depend on what everyone ought to value, independently of its relation to himself' (1991: 40). As agents, we act on agent-relative reasons because even though actions affect what happens in the world, in the first instance one's choice is necessarily between one's own actions. However, each of us also has an objective self which views the world in detachment from one's particular perspective. Consequently, the objective self chooses between different possible states of the world and its choice is based on agent-neutral reasons. So, moral conflict is due to the fact that 'every choice is two choices', every choice is at once a choice between actions and between states of the world. Moral conflict arises when the agent's choice concerning what to *do* conflicts with the objective self's choice concerning what should *happen*.

Nagel thus explains that consequentialism gives primacy to the agent-neutral values on the basis of which the objective self chooses between world-states. In contrast, deontological theories give primacy to certain agent-relative reasons which restrict agents from acting in certain ways. His own position is both complex and modest. It does not allow for a general championing of one kind of reason over another. Against consequentialism, Nagel argues that not all values are agent-neutral. But he also voices some uncertainty about whether there really are agent-relative reasons. However, while he does not argue for their existence directly, he explains them, especially the most problematic deontological ones, in lucid and compelling terms. The modesty of Nagel's position lies in his conviction that we are far from a developed moral outlook. In contrast to his view that subjective and objective facts are irreconcilable, Nagel believes that it is possible, in principle, to develop our agent-relative values to be more consonant with agent-neutral values. However, as we will see in Nagel's discussion of political theory, he finds little hope that the actual conditions of human life will allow us to school our moral outlook (see Moral realism).

6 Political philosophy

While political theory is typically understood as dealing with the relationship of the individual and society, Nagel holds that it deals with the relation of each individual to themselves, since each one of us occupies both a particular individual viewpoint and the detached standpoint of the collectivity. So the problem of designing morally justified social institutions that would reconcile the conflicts between the individual and society is the problem of designing social institutions that would allow each of us to reconcile those two standpoints within ourselves.

Nagel argues that a justified political system would be a unanimously supported, strongly egalitarian one, because in taking on a more objective standpoint, we see that everyone is equal not only in the sense that no person's life matters any more than any other's, but in the sense that it is more important to improve the lives of the worse off than to add to the advantages of the better off. The conflict between this impersonal, strongly egalitarian dictate and our personal motivation to lead our own lives could be resolved by general principles that can be universalized in a Kantian manner: principles that each of us can will to be universal laws. That is, we need to find our way to wanting 'to live by principles that anyone can accept' (1991: 48).

Nagel holds that we need political institutions to help integrate and develop our dual motivations. He suggests that the 'general form' of a solution is 'a moral division of labour between individuals and institutions'. According to such a division, the social institutions in which we participate would allow us to act on our impartial, egalitarian motives. This would allow us to act on our personal motives outside of our social roles. However, Nagel argues pessimistically against the possibility of developing such institutions given the initial duality of motives. In sum, since he is drawn to a strongly egalitarian social ideal, to whose recognition the duality of standpoints is necessary,

but to whose realization the duality of standpoints seems to present great obstacles, Nagel does not see how to embody that ideal in a morally and psychologically viable system (see Equality).

List of works

Nagel, T. (1970) *The Possibility of Altruism*, Oxford: Clarendon Press.(Incorporates material from Nagel's B.Phil. and Ph.D. theses. Focuses on the motivational basis for morality, arguing that altruism is a basic rational requirement on moral action. This first work gives a stronger role to the objective standpoint and its deliverances than does Nagel's subsequent work in moral philosophy.)

Nagel, T.(1979) *Mortal Questions,* Cambridge: Cambridge University Press.(Essays on a wide variety of topics that were published between 1969 and 1979, including the highly influential 'Moral Luck' and 'What is it like to be a bat?'. Several essays deal with issues of public policy and are motivated by events and policies associated with the Vietnam War.)

Nagel, T., Cohen, M. and Scanlon T. (eds) (1980) *Marx, Justice and History*, Princeton, NJ: Princeton University Press.(Essays by a variety of authors in *Philosophy and Public Affairs* from 1972 to 1979 that bring together contemporary analytic moral philosophy and Marxist social theory.)

Nagel, T. (1986) *The View From Nowhere*, Oxford: Oxford University Press.(Presents Nagel's systematic and comprehensive treatment of the fundamental philosophical issues in terms of the essential duality between objective and subjective points of view and the distinctive facts and values that they make available.)

Nagel, T. (1987) *What Does It All Mean?*, Oxford: Oxford University Press.(A concise and 'direct' or nonhistorical introduction to nine basic philosophical problems.)

Nagel, T.(1991) *Equality and Partiality*, Oxford: Oxford University Press.(Incorporates Nagel's 1990 John Locke Lectures. A detailed development of Nagel's proposal that the central problem of political theory- that of reconciling the conflicts between the individual and society - is posed by the division between these standpoints within each individual and needs to be addressed accordingly.)

Nagel, T. (1995) *Other Minds: Critical Essays, 1969-1994*, Oxford: Oxford University Press.(These essays focus on the views of particular philosophers in the philosophy of mind and in ethics and political theory. In the philosophy of mind, Nagel addresses the views of Freud, Wittgenstein, Chomsky, Fodor and Dennett among others. In ethics and political theory, Nagel treats the views of philosophers such as Rawls, Nozick, MacIntyre and Williams as well as Schelling and Kolakowski. The book opens with a fascinating intellectual autobiography entitled 'Introduction: The Philosophical Culture'.)

Nahmanides, Moses (1194-1270)

One of the most influential medieval Jewish thinkers to engage with the philosophical tradition, Nahmanides was also a leading Talmudist, biblical exegete, and a founding figure of the Jewish mystical tradition (Kabbalah) that emerged in thirteenth-century Spain. Generally critical of Aristotle, he was deeply influenced by predecessors such as Moses Maimonides. As the leading rabbi in Catalonia, Nahmanides played a central role in the 'Maimonidean controversy' of 1232-3, a dispute that raged over the permissibility of philosophical study. He was also at the centre of the 'Barcelona disputation' of 1263, conducted with the apostate Pablo Christiani over the issue of philosophically motivated allegories.

Unlike his Provençal contemporaries, Nahmanides wrote neither free-standing philosophical treatises nor commentaries on Graeco-Arabic philosophical texts. Instead, he developed his original metaphysical views in sermons and his highlt influential biblical commentaries treating such topics as miracles, providence and idolatry. The commentaries proved especially influential through their thematic treatments of philosophical questions raised by the biblical text and for their suggestive expositions of mystical and theosophical ideas.

1 Relation to the philosophical tradition

Moses Nahmanides, Rabbi Moses ben Nahman, known in Hebrew texts by the acronym 'Ramban' and in Christian literature as Bonastrug de Porta was born in Gerona, Catalonia, and died at Acre in Palestine. He became the leading Catalonian thinker in the intellectually tumultuous period following the publication of Maimonides'*Guide to the Perplexed*, whose Hebrew translation in 1204 by Samuel ibn Tibbon brought about the first major encounter of Jewish thinkers in Christian Spain and Provence with Graeco-Arabic and specifically Aristotelian philosophy. Although standardly portrayed as a conservative defender of rabbinic traditions, Nahmanides showed a nuanced ambivalence towards rationalism in general (which had a long indigenous Andalusian tradition) and the thought of Aristotle and Maimonides in particular. In the 'Maimonidean controversy' of 1232-3 Nahmanides joined ranks with the anti-rationalist camp to forbid unrestricted public study of philosophy, but he also vigorously defended Maimonides and attempted to prevent the banning of the *Guide* and Maimonides' philosophical oopening sections of his fourteen-volume code of Jewish law, the *Mishneh Torah*. Comparable dualities run throughout his thought. He repeatedly criticized Aristotle for his empiricism and doctrine of the world's eternity and reproved Maimonides for his challenges to rabbinic theological traditions. But his own doctrines are constructively influenced by the philosophy of the *Guide*. His decision to present his ideas primarily in commentaries on Scripture is exemplary of his outlook: philosophical reasoning may be essential to the strengthening of belief but it must remain subservient to divine revelation and the revealed tradition. Nahmanides repeatedly emphasizes the importance of rational understanding. In *Sha'ar ha-Gemul (The Gate of the Reward)*, he recalls the words of Saadiah Gaon, in *Kitab al-mukhtar fi'l-amanat wa'l-'i'tiqadat (The Book of Critically Chosen Beliefs and Opinions)*, attacking those who spurn philosophical reflection as 'fools who despise wisdom' (see *Kitvei ha-Ramban* II: 21).

Nahmanides' cautiously critical stance towards philosophy stands out in his influential views on midrash *aggadah*, the immense literature of non-legal (non-*halakhic*) rabbinic exegesis, homilies and imaginative writing (see Midrash), whose interpretation and authority were centrally at issue in both the Maimonidean controversy and the 'Barcelona disputation' of 1263. In the latter event, Nahmanides was summoned to engage in a public argument with the apostate Pablo Christiani. Maimonists viewed the rabbinic midrash (and the non-legal sections of the Hebrew Bible) as philosophical allegories, contemplation of whose truths was the highest form of worship. Anti-Maimonists insisted on the primacy of practice, the life of the divine commandments or *mitzvot*. Rejecting philosophically motivated allegories as a potential source of antinomianism, grounded in a suspected substitution of contemplation for religious observance, they urged that midrash *aggadah* be accepted virtually at face value, even when its mythic and supernatural claims violated reason. In the Barcelona disputation, Christiani put *aggadic* and scriptural materials to allegorical use in behalf of Christianity, rendering the allegorical method all the more suspect. Nahmanides' position in both confrontations was novel. His rationalist sensibilities forbade him to interpret all *aggadah* literally. Following his Andalusian predecessor Abraham ibn Ezra, he subjected *aggadah* to the same interpretive standards of philology, grammar and reason that he applied to biblical interpretation itself. But he undercut the antinomian potential of philosophical allegorization and the evangelical impact of Christian misappropriations by denying that midrash *aggadah* is authoritative. Relying on some imaginative philology, he

argued that *aggadah* is merely homiletic - or, even less, ‘things one man tells another’. It is never authoritative in belief or practice, as are *halakhic* texts. This conservative and anti-Maimonidean approach deeply influenced later Jewish dogmatics and polemics by restoring action rather than belief as the essence of Judaism. The immediate consequences for Nahmanides were not, however, favourable. While the disputation was a theological victory for him, his Dominican opponents responded by charging him with abusing Christianity and he was forced to flee to Palestine.

Nahmanides’ turn to mystical theosophy reflects his opposition to the Maimonists’ assumption that the deepest truths of the Law are somehow coextensive with the received tradition of Aristotelian physics and metaphysics. Nahmanides presents Kabbalah as an indigenous Jewish alternative to Graeco-Arabic philosophy, a *prisca philosophia* (archaic or antidiluvean philosophy) based on a revealed (and hitherto oral) tradition rather than reason, and a fixed canon of theosophic exegeses of biblical verses and commandments (see Kabbalah). Thus, in place of Maimonides’ account of evil in terms of matter, he proposes a theodicy based on transmigration; instead of Maimonides’ anthropological-historical account of the Temple sacrifices, he turns to the theory of divine emanations (Sefirot).

2 Metaphysics: miracles and divine providence

Perhaps the most original and philosophically interesting of Nahmanides’ doctrines is his theory of revealed and hidden miracles (see Miracles). Revealed miracles such as the splitting of the sea in Exodus 14 violate the observed regularities of nature and cannot be explained by natural causes but must be attributed to divine intervention. Nahmanides believed that the Bible provides reliable evidence of such manifest miracles. Typically witnessed by the entire community, they provide empirical verification for the three fundamental principles of Judaism: *ex nihilo* creation, divine knowledge, and providence. Such empirical appeals, rather than rational demonstrations, are Nahmanides’ primary epistemic grounds for faith. In the case of creation, for example, he argues against Aristotelian eternalism, suggesting that if the world were eternal, nature as it is would be necessary and God would be unable to shorten the wing of a fly if he wished. But this consequence is baldly disconfirmed by the experience of revealed miracles in which God has violated presumed necessities of nature. Eternalism, then, is refuted and, Nahmanides concludes, the world must have been created *ex nihilo*. To be sure, this conclusion does not follow. As Maimonides (from whom Nahmanides drew this argument) observed, the existence of miracles does not exclude a third alternative, the Platonic theory of *formatio mundi*, creation from eternal matter. Indeed, from other statements, in which Nahmanides claims that what was created *ex nihilo* was matter, or potentiality, without form, it is not clear how well he understood Aristotelian metaphysics or its differences from Platonic or Platonizing doctrines. However, his argument for creation *ex nihilo*, which appeals to miracles as empirical data, is still of interest. After repeatedly describing Aristotle as an empiricist who believed only in what our senses perceive, Nahmanides tries to turn empiricism against Aristotle, arguing, in effect, that one cannot be both an empiricist and an eternalist.

Nahmanides’ doctrine of hidden miracles underlies his theory of providence - specifically, of divine rewards and punishments (see Providence). Such miracles violate no observed regularities and may even have obvious explanations in terms of intermediate natural causes. The same events, however, can be explained by attributing them to God, who brings them about as rewards or punishments of the absolutely righteous and wicked. Such direct attributions, Nahmanides argues, are simpler and more sensible than the naturalistic alternatives: while caused by God under conditions we may never know in full, hidden miracles follow in law-like patterns as consequences of human actions; and because they occur only in response to the acts of absolutely righteous and wicked persons, not the ordinary individuals who fall between these two extremes, Nahmanides can uphold a nature whose laws govern these ordinary people. So despite some strong rhetoric in which he appears to deny the existence of nature *tout court*, Nahmanides does not seem to be an occasionalist. Rather, his doctrine seems to expand upon Maimonides’ theory of ‘natural’ providence, whereby all species (and ordinary individuals as their members) are endowed with natures to provide for their wellbeing, and certain perfected individuals can transcend the vicissitudes of nature, achieving an additional kind of individual providence. The main differences from Maimonides here turn on the nature of that individual perfection and on the role of miracles. For Maimonides, individual providence is consequent on intellectual development: only those who become ‘acquired intellects’ rise (in that measure) above matter and the conditions of natural evil. Miracles have no place in this process. Nahmanides, by contrast, makes individual reward and punishment consequent on moral character and religious

practice. He offers no metaphysical explanation of its operations but makes miracles its unseen vehicles. He takes over the structure of Maimonides' account but substitutes more traditional rabbinic categories for Aristotelian ones.

Paralleling the individual providence that attends the actions of the absolutely righteous and wicked, Nahmanides affirms a special providence over the nation and land of Israel. This special providence is described by Nahmanides in relation to his views on astrology and astral determinism, theories shared by many of his Andalusian predecessors and contemporaries, with the notable exception of Maimonides. On Nahmanides' theory, there exist real forces associated with the constellations created by God to govern the nations. There is also a hierarchy of angels and demons. The people and land of Israel, however, remain directly under the dominion of God. It is forbidden as idolatry for Jews to worship any other power, not because such powers do not exist but because no other power is the rightful Lord of Israel. Similarly with the complex hierarchy of powers, Kabbalistic Sefirot, *within* the deity. It is a kind of idolatry to worship any of these emanations apart from the deity as a whole. Such worship is tantamount to denying God's unity.

3 Hermeneutics and explanation of the divine commandments

Nahmanides pursues three distinct levels of biblical exegesis with exceptionally systematic care. He typically offers (1) a literal interpretation (*peshat*) according to the philologically determined senses of words, syntax, historical context and narrative structure; (2) an interpretation containing moral or political wisdom (*hokhmah*); and (3) a riddle-like secret theosophic interpretation (*sod*), which he calls 'the way of truth'. At this third level, he was the first to incorporate Kabbalistic mysteries, even if only allusively, in an exoteric commentary. Some of his most original and enduring exegetical contributions, however, work at the first two levels. He was the first, and perhaps the only, medieval Jewish exegete to offer typological interpretations like those found in Christian exegesis. In reaction to Maimonides' radical devaluation of literal meanings, he also did much to restore the status of *peshat* and to enrich its traditional scope, making it more thematic and conceptual, and at times even subsuming the philosophical and mystical exegeses of the text.

Like Maimonides, Nahmanides was a vigorous advocate of inquiry into the reasons for the *mitzvot*, although he often disagreed with the explanations of the *Guide to the Perplexed*. Applying his exegetical method, he argued that, besides their moral, political and commemorative purposes, the commandments have an inner theurgic function in serving divine needs. Here, as in his exegesis, his multi-levelled explanations, ranging from the popular to the esoteric, and his brilliance as a stylist made Nahmanides an exceptionally influential writer.

Nancy, Jean-Luc (1940-)

Jean-Luc Nancy has disclosed significant political and social dimensions to the general project of deconstructing Western philosophy. Existence does not precede essence, according to Nancy; existence is without essence, and it is therefore impossible both to represent existence and to exist alone. Being is always 'being in common'. The task of philosophy consists in rethinking the commonality of being without relying on any prior conception of identity, unity or wholeness. 'Being in common' means that nothing - no substance, no identifiable trait- is held in common. The absence of a common substance or spiritual identity does not then generate a command to make up for this lack by means of socially useful work. As the exposure of each singularity to its ungrounded commonality, 'being in common' is the always surprising 'fact' upon which all of Nancy's investigations into philosophy, literature, psychoanalysis and political phenomena are oriented.

As a professor of philosophy at the University of Human Sciences in Strasbourg, Jean-Luc Nancy remains on the periphery of contemporary academic philosophy in France. The proximity of Strasbourg to Germany is reflected in many aspects of his work. Not only has Nancy translated seminal texts of German philosophy and literary theory, his writings constantly engage those post-Kantian German thinkers - Hegel, Marx, Nietzsche, Freud, Heidegger - who declare, each in his own way, that philosophy has come to an end. Both his critical commentaries on philosophical texts and his attempts to rethink the terms in which political and social philosophy are cast take their point of departure from what Heidegger called 'the end of philosophy'. This phrase means, for Nancy, that the resources of representation have been exhausted: philosophy can no longer claim to bring the essence of a phenomenon into view on the basis of a unified subject of any sort. Since philosophy has come to an end, and since it cannot be simply overcome, there is no choice but to repeat the history of philosophy. There are two ways to undertake this repetition: either ignore the end of philosophy and proceed to rework previous philosophical positions, or expose philosophy to its end and thus develop a 'finite' thought of community, sharing, meaning, freedom - to name a few of the topics Nancy has explored in detail. By re-examining these topics from the perspective of what Jacques Derrida has called the 'closure of metaphysics', Nancy has made a significant contribution to the general project of deconstructing the history of Western metaphysics.

Nancy's readings of philosophical texts closely match those of Derrida. What distinguishes his writings from other versions of 'deconstruction' (see Deconstruction) is his decision to rethink certain topics often associated with existentialism (see Existentialism). By reconsidering such topics as existence, abandonment, embodiment, freedom, community and communism on the basis of a more rigorous reading of Hegel and Heidegger than any of the existentialists could claim, Nancy has been able to disclose significant political and social dimensions to the project of deconstruction. His attempts to rethink these terms are all oriented on one 'fact': existence is without essence. Nancy does not proclaim, as does Sartre, that 'existence precedes essence' but that existence precedes, exceeds and succeeds itself, for existence is sheer non-coincidence with itself. From its inception, philosophy has interpreted the 'fact' that existence precedes itself by representing it in terms of a subject that underlies and is thus prior to its various attributes and accidents. Even when the subject is viewed as an ideal or as an incomplete project, the basic structure of 'infinite' and thus 'onto-theological' thought remains intact: the subject grounds itself in its prior or future essence. The 'finite thought' Nancy proposes never proceeds beyond the 'fact' that existence is without essence and without ground. Forever receding from representation, existence consists in an exposure to the groundlessness of being.

One of the most innovative aspects of Nancy's work is the way in which it brings the existential analysis of *Being and Time* into conjunction with Heidegger's late reflections on *Ereignis* ('event of appropriation') (see Heidegger, M. §5). Nancy presents being (*être*) not as the essence of things or the ground of phenomena but as a 'free' and 'generous' event: being takes place as existence. Since existence cannot support itself, it can never be alone or on its own. 'Being in common' thus defines 'finite' existence. No one participates in any*thing* when existence takes part in, or 'shares' being. Existence can even be understood as co-exposure to the absence of anything held in common as long as this absence is not then represented as something communal or 'socially useful' work could seek to repair. If 'being in common', which Nancy associates with 'the political' as opposed to 'politics', is represented in terms of a programme for securing what society lacks, it - and therefore the 'political' - are destroyed. Drawing on Kant's thesis of radical evil, Nancy presents the destruction of 'being in common' in

L'Expérience de la liberté (1988b) (*The Experience of Freedom*, 1993) as 'wickedness'.

Many of Nancy's later writings explore the bodily character of 'being in common'. Thought itself is presented as bodily: to think (*penser*) is not simply to weigh (*peser*) various options but to be weighed down. The kind of thinking that takes its point of departure from the 'fact' that existence cannot be represented is indistinguishable from touching, for, according to Nancy, to touch and to be touched are two modes of being at the limit of representation. Nancy thus counters the Kantian conception of thought as spontaneity with a 'passive' thinking whose 'passion' consists in an exposure to an always antecedent sense. *Sens* ('sense', 'meaning'), according to Nancy, precedes and exceeds all signification; it cannot be grasped, granted, discovered or produced. As long as the body is the locus of sense, it cannot be securely located, only absolved, shared, and parcelled out: 'There is no whole, no totality of the body - but its absolute separation and sharing out. There is no such thing as *the* body. There is no body' (1993b: 207). All of Nancy's explorations of the political and social dimensions of deconstruction assign themselves the same task as his writings on 'the body': they gesture toward what allows for and what destroys 'being in common'.

Narrative

Narrative, in its broadest sense, is the means by which a story is told, whether fictional or not, and regardless of medium. Novels, plays, films, historical texts, diaries and newspaper articles focus, in their different ways, on particular events and their temporal and causal relations; they are all narratives in the above sense. Accounts of mathematical, physical, economic or legal principles are not. A narrower sense of narrative requires the presence of a narrator mediating between audience and action, and contrasts with imitative discourse wherein the action is presented directly, as in drama. The boundary between narration narrowly construed and imitation is disputed, some writers arguing that apparently imitative forms are covertly narrated.

Attempts have been made to characterize fictional narratives in linguistic terms; another view is that fictions are things which have certain (intended or actual) effects on the audience. Theorists of narrative have mostly concentrated on narratives of the fictional kind and have developed a complex taxonomy of the various narrative devices, some of which are discussed in more detail below. Recently, pressure has been placed on the distinction between historical and fictional narrative by those who believe that history is nothing distinct from the various and conflicting narrative versions we have. It has also been argued that value accrues to an agent's life and acts when those acts conform to a conception of that life as exemplifying narrative.

1 Narrative and fiction

On one view, narratives are identifiable as fictional by their use of distinctively fictional language. But while devices like free indirect discourse (for example, 'She was damned if she would go') may be peculiar to fiction, there are fictions which do not employ them and which are linguistically indistinguishable from nonfiction. Nor can fictionality be explained in terms of lack of reference or truth, since fictions often concern real people and events, while much nonfiction is false. An alternative view is that fictional narratives function in a certain way. On one version of this theory, the reader is intended to *imagine* the occurrence of the events described in the narrative, rather than to treat those descriptions as assertions judgeable by standards of evidence and truth. This suggestion will be employed in the next section.

2 Narrative theory

Work on the theory of narrative has largely concentrated on fictional narratives; the results so far constitute a suggestive taxonomy rather than a systematic theory. An important distinction should be made between the story presented and the discourse that presents it. For example, *anachrony* occurs when the temporal order of events as they happen in the story is not reflected in the discourse; we hear first of A and then of B, though B occurred before A. Again, it may be a feature of the discourse that the story is told by a certain narrator, or from the point of view of a certain character; these are not features of the story itself unless it is part of the story (or, as I shall say, it is fictional) that someone with knowledge of these events performs an act of telling.

Narration and point of view are themselves distinct concepts; the narrator may tell the story from the point of view of a character, with shifts in point of view without change of narrator. The narrative is said to be 'focalized' through a character when the narrator presents the story as it is experienced by that character. It is sometimes said that the story is focalized through the narrator when there is no character through whom it is focalized. This is confusing, because the narrator's act of telling is not in general an act of experiencing the events of the story. Other unhelpful extensions of focalization have been made; it has been said that when character A hears character B speak of character C, C is focalized at the third degree. But C's relation to B and to A in this case is not at all like the relation of a character to the narrator who narrates from that character's perspective (Chatman 1986). Focalization needs a treatment of greater care and parsimony than it has yet received.

The narrator is often said to be distinct from the author. (Until now, I have been using 'narrator' in a sense which does not distinguish them.) The narrator is a construct of the work itself, and either within the world of the story tells us what they know or believe to be true (or, as in an unreliable narrative, tries to mislead us about what has happened), or, alternatively, from outside that world, tells us a fictional story. Watson is the internal or 'intradiegetic' narrator of the Sherlock Holmes stories, while the narrator of *Tom Jones* is external or 'extradiegetic'. The author is also distinguished from the implied author, who is an imagined creature constructed

by the reader as the personality who seems to have written this work; the implied author of *Anna Karenina* might be more tolerant, generous and understanding than the real Tolstoy apparently was.

Could the implied author take on the role otherwise assigned to the extradiegetic narrator? Advocates of the extradiegetic narrator point to works in which the narrator's outlook is one the reader seems to be expected to reject; it is natural to say that there is in such cases a tension between narrator and implied author and consequently that we must conceptualize the work by invoking two distinct personalities. But cases of this kind can be handled without appeal to the extradiegetic narrator, by assuming that the implied author is speaking ironically; it is the implied author who speaks, but what is said is intended by that same speaker to be ridiculed or rejected. We can, therefore, dispense with the idea of an extradiegetic narrator in favour of the implied author. Intradiagetic narrators, on the other hand, are certainly present in some fictions; Watson, in the Holmes stories, is one. In other cases no narrator within the story is evident. Theorists have sometimes postulated hidden narrators, intra- or extradiegetic, for such works on the grounds that the events of the story must be told to us by someone (Chatman 1990: 133). Since the argument just given abolishes the extradiegetic narrator, let us concentrate on the claim that every fictional narrative requires an intradiegetic narrator, even where no such narrator is apparent in the text. In assessing this postulate, it is important to distinguish between what is true and what is fictional. It is true of all stories that they are told by someone, namely the author. The author's act of telling is an invitation to us to imagine various things, and these things jointly constitute what is fictional in the story. Among the things we may be asked to imagine is that someone with knowledge of the events of the story is telling them to us as fact; in that case we have a fictional story with an intradiegetic narrator. On the other hand, we may be invited to imagine merely that the events of the story occurred and that no one in particular is telling them to us. Once we distinguish really telling a fictional story (something the author does) from fictionally telling a true story (something an intradiegetic narrator does) we see that while every fictional story is told as fiction, not every such story is fictionally told as fact. If the reasoning of this paragraph is correct, no works have extradiegetic narrators, only some have intradiegetic ones, and consequently some narratives have no narrator.

In dispensing with a narrator we need not reject the idea that a narrative needs to be understood as the product of an intending agent. But some writers in the structuralist tradition have claimed to identify a kind of writing that lacks the devices which signal the presence of a writer or speaker, such as indexicals or the past tense. They say that narrative in this sense is objective (or purports to be), and the events of the story 'speak themselves' (Benvenista 1966). This is a mistake. Even writing that contains no verbal indicators of agency presupposes the existence of one who speaks or writes, for something counts as language - and not as meaningless marks or sounds, - only if it was produced by an agent intending to conform their sound/mark production to the conventions of a language.

3 Narrative and antirealism

Antirealists (see Realism and antirealism §2) reject the idea that there is a determinate reality, largely independent of human activity and conception, to which our cognitive powers give us only limited access. They claim that the world is indeterminate in those regions inaccessible to our investigations or - in a more extreme version - multiple and conflicting in a way that mirrors our own multiple and conflicting conceptions of the world. Some antirealists have supposed that science, biography and history are species of fiction, giving rise to narratives unconstrained by correspondence with reality.

One version of this argument holds that historical narrative imposes on a series of events features that the series does not intrinsically possess, by means of selectivity, teleology and closure. Narrative selects among events, highlighting some and placing others in the background; but the events themselves do not stand in relations of salience and no event is intrinsically more important than any other. Narrative is teleological in so far as the reason for including events in a narrative is their contribution to outcomes distant from those events and identifiable, once again, only in terms of interests that are variable across cultures, times and individuals. Narrative imposes closure on events by claiming to identify a natural stopping place for the narrative; in fact there are no natural stopping places intrinsic to the events themselves, but only relative to the events as they are ordered and selected by interest. Let us call such features 'plot-like', so as to remind us of the antirealist's presumption that they are features which push historical writing into the realm of the fictional.

One realist response would be to argue that plot-like features, while not intrinsic to the historical events

themselves, are none the less real, relational features of those events, much as colours are said to be real, relational properties of things, since the colour of a thing depends on the kind of visual experience it causes us to have. And just as an account of the colours of things can be thought of as reporting matters of fact, so the attribution of plot-like features to events and their relations in an historical narrative counts as (potentially) fact-stating. On this view, narratives which seem to disagree in their attributions of plot-like features may genuinely contradict one another, and only one narrative can be right. But another possibility for the realist is that the appearance of disagreement is the result of the failure of the plot-like features to be properly relativized. Such a conflict would dissipate if what is said to be significant according to one narrative and insignificant according to another is intended to be understood as significant from one point of view according to the first narrative, and insignificant from another point of view according to the second.

A more moderate realist response admits that plot-like features are not genuinely features of the historical events themselves. It insists, however, that there is another set of features (hereafter 'truth-making' features), which are genuine features of the events themselves, and that historical narratives can be thought of as correct if and only if they attribute these features correctly. Correctness of a narrative in this sense is independent of its plot-like aspects, in that narratives will only count as rivals when they differ over attributions of truth-making features. When they differ over the attribution of plot-like features, they merely count as alternatives. Thus two correct but different narratives would be like two photographs of the same scene taken from different angles. Each photograph/narrative is correct as far as it goes, though one might be more comprehensively correct than the other. Perspective-related differences between the pictures that affect the apparent spatial relations of objects will not count as disagreements between them. Likewise, differences between the narratives in respect of plot-like features will not count as genuine contradictions.

4 Narrative and value

It has been argued that our lives constitute narratives, and that this gives them value. It is difficult to decide what literal truth there is in this idea. How could a life *be* a narrative, rather than simply contain the material for a narrative? If narrative is what someone, perhaps the agent, tells of that life, in what sense does the value of the narrative constitute the value of the life? We know from literature that there can be valuable narratives of bad or otherwise valueless lives. Perhaps a life can be a narrative in this sense: the agent's actions are determined by the agent's conception of past and present actions and future goals as part of a coherent narrative; the agent's life would then be lived 'as narrative'. We can only guess how many lives are in this sense narrative, and in what proportions value is distributed between lives lived as narrative and lives not: of the former many would be reduced in value to the extent that the subject's narrativization of their actions and goals was the result of misunderstanding or self-delusion. Another suggested association between narrative and value is that our present and future actions can affect the value of past actions, for instance in cases where a bad act is to some extent redeemed by its role in the actor's subsequent change of heart. To make a thesis about narrative of this it is not, however, sufficient to say that later acts can affect the value of earlier ones, for that could be true even when the change of heart is related to any story-telling on the subject's part or on anyone else's part. It must be claimed in addition either that (1) value is transmitted from later acts to earlier ones *only* when the later act is the outcome of the agent's conceiving the past act within a narrative framework, or, more modestly, that (2) while value can accrue to the past act without any such narrativizing taking place, additional value accrues when the later act *is* the outcome of such narrativizing.

Nation and nationalism

No one observing political events in the world today could deny the continuing potency of nationalism. Many of the most intractable conflicts arise when one national community tries to break away from another, or when two such communities lay claim to the same piece of territory. Yet to outsiders the basis for such conflicts often seems mysterious. People are prepared to fight and die for their nation, yet what exactly is this 'nation' that commands such loyalty? Why should it matter so much that a person is governed by leaders drawn from one community rather than from another?

Philosophers are often inclined to dismiss nationalism as having no rational basis, but as resting merely on tribal instincts and brute emotions. Such a response overlooks the different forms that nationalism has taken: in particular, the contrast between authoritarian nationalism, which allows national cultures to be imposed by force and which may justify acts of aggression against neighbouring peoples, and liberal nationalism, which upholds the rights of individuals to form political communities with those with whom they feel identified and to protect their common culture. We need to examine carefully the arguments that have been advanced by nationalist thinkers in order to decide which form of nationalism, if any, is rationally defensible.

1 What is a nation?

Defining 'nation' has proved a difficult task for political philosophers. In common speech 'nation' is often used loosely to mean 'state', as it does in phrases such as 'United Nations'. But this loose usage is not helpful in political philosophy, one of the central questions of which is whether there are indeed such things as nations, and if there are, whether nations have a valid claim to be self-governing - or to put it more crudely, whether each nation is entitled to have its own independent state. When questions such as these are asked, 'nation' must refer to something that exists apart from and prior to the political institutions of the state.

A nation, we may say, is a community of people who recognize that they are distinct from other communities and wish to control their own affairs. But a community of this sort is clearly very different from the small face-to-face communities that may first spring to mind when the idea of community is invoked (see Community and communitarianism §1). Since I shall never know more than a tiny fraction of my fellow countrymen personally, how can I say that we form a community? What is the source of unity that holds nations together?

Broadly speaking, two answers have been given to this question. On one side stand those who take a subjective view, claiming that nations are essentially voluntary associations of people held together simply by the continuing will of their members. We form a nation because we want to be politically associated. The reasons behind this desire are irrelevant: all that finally matters is that each of us wants to associate with this group of people rather than that. On the other side we find those who maintain that nations are marked out by certain objective characteristics that their members share - by racial descent, by language, by religion, by common traits of character, and so forth. On this view it makes sense to speak of dormant nations whose members have in common whatever is taken to be the essential defining characteristic of nationality, but who as yet display no consciousness of nationhood or desire to form a political community.

Neither of these answers seems adequate as it stands. Objective accounts of nationhood fall down when we take the proposed characteristics one by one and see that none is adequate to distinguish all those communities that we recognize to be separate nations (Renan 1939). If we take the objective view and focus on a feature such as language, we find on the one hand that there can be distinct nations with a shared language - the English-speaking countries for instance - while on the other hand there can be bi- or tri-lingual nations such as Belgium or Switzerland. The subjective account avoids this pitfall, but this does not clear up the mystery of why people should care so much who they associate with politically. A more adequate answer must combine elements of both viewpoints. A nation exists when its members recognize one another as belonging to the same community and as bearing special obligations to one another, but this is by virtue of characteristics that they believe they share: typically, a common history, attachment to a geographical place and a public culture that differentiates them from their neighbours.

Because nations are communities on a large scale, they are inevitably 'imagined communities', in Benedict

Anderson's evocative phrase, meaning that they depend for their existence on collective acts of imagining which take place through media of communication such as books, newspapers and television (Anderson 1990). It is from these media that we acquire our understanding of what it means to belong to this particular nation. Does this imply that national communities are after all spurious? This by no means follows, although it may justify a degree of scepticism about the received content of national identities. First, such identities usually incorporate a certain proportion of historical myth, in the sense that past events are interpreted in such a way as to highlight their continuity with events in the present. Although we actually know very little about our thirteenth-century ancestors, for example, we are invited to see their heroic struggles against their neighbours as the precursors of our own. Second, nations tend to exaggerate their own homogeneity, supposing that every member conforms more or less precisely to the cultural stereotype that forms part of the national identity. Third, national identities are to some degree able to be manipulated by powerful groups, especially political leaders, whose command of the media enables them to refashion the content of the imagining to suit their purposes. No political leader can invent a nation where one does not exist; but it may be possible to persuade a nation that its legitimate territorial boundaries stretch more widely than it had hitherto imagined, or that a particular subcommunity - an ethnic group for instance - that has long lived happily as part of the nation does not after all belong there. The practical consequences of such refashioning may be very serious, as experiences of the twentieth century readily illustrate.

For reasons such as these, most philosophers have been ambivalent both about the validity and about the practical relevance of national identities.

2 The evolution of nationalism

Nationalism is primarily a phenomenon of nineteenth- and twentieth-century political thought. Its constituent ideas, however, stretch back much further in time. Among the Jews of the Old Testament and among the ancient Greeks we find the sense of belonging to a distinct people marked off from the rest of the world by special characteristics - an embryonic sense of national superiority (Kohn 1944, ch. 1). In the classical period, moreover, patriotism was regarded as a leading virtue. Patriotism is not the same as nationalism: it means a love of one's native country and a willingness to sacrifice oneself to defend it, but it need not invoke the idea of a self-conscious nation discussed in §1, nor need it imply that the country in question should enjoy political self-determination. Like nationalism, however, patriotism involves the idea that one owes special obligations to one's compatriots, that one should be willing to protect and defend them at the expense of outsiders - an ethical stance that many philosophers have found difficult to accept.

Nationalism proper began to emerge in the second half of the eighteenth century, when to the ideas of distinct nationhood and patriotic loyalties were added the idea that nations are the source of legitimate political authority. There is a close link here between nationalism and the doctrine of popular sovereignty, which replaced the older belief that political authority flowed downwards from the king or the emperor (Kamenka 1976). Rousseau (§3) provides a striking illustration of this link, holding on the one hand that the general will of the people was the only legitimate source of legislative authority, and on the other that every citizen must be taught to love their native country before all else: 'That love makes up his entire existence: he has eyes only for the fatherland, lives only for his fatherland;… the moment he has no fatherland, he is no more' (Rousseau 1770-1: 19).

In these words, Rousseau anticipates the more extreme forms of nineteenth-century nationalism. The contribution of the early nineteenth century was the Romantic belief that each nation formed an organic unity, with its own soul and its own special destiny. Of particular importance was Herder (§§2, 6), whose expressive theory of language underpinned his idea that each nation was the bearer of a unique culture, immersion in which was the only path to human self-fulfilment. Herder's nationalism was primarily cultural rather than political; he wanted to see each national culture thriving in peaceful coexistence with its neighbours, and he had no sympathy with the aggressive militarism of the Prussian state. None the less he continued to link nationality and popular self-government: 'The roses for the wreath of each nation's liberty must be picked with its own hands, and must grow happily out of its own wants, joys, and love' (Kohn 1944: 431). This message found a ready response among those cultural minorities of Europe struggling for political independence from long-established empires.

Cultural nationalism and political self-assertion coalesced in the later thought of Fichte (§7). Fichte combined three doctrines: the idea that nations were organic wholes, each with its own language and culture; that each person owed supreme loyalty to their own nation - that indeed freedom consisted of identifying oneself with the

higher cause represented by the nation; and that each nation had its own peculiar mission. Fichte also attenuated the link between nationalism and popular self-government: national leaders might be justified in using coercive methods of education in order to create strong and united peoples. Here we see the foreshadowing of an authoritarian form of nationalism which is willing to override liberties domestically in the name of national unity, and which may justify acts of aggression against neighbouring states in the name of national destiny.

The same period also witnessed the growth of a liberal form of nationalism, according to which the cause of national independence and the cause of political liberty go hand in hand. This was the view of Mazzini, the father of Italian nationalism, and it was echoed by J.S. Mill, who in *Considerations on Representative Government* (1861) emphasized the role played by national sympathies in checking the power of government and making free institutions workable. Liberal nationalism treats all nations as having equally good claims to self-determination, resists ideas of ’national destiny’ and argues that national cultures will flourish best when freedom of expression and other liberties are secure.

The subsequent history of nationalism can be seen as a struggle between authoritarian and liberal forms of nationalism. The latter can be seen at work in the doctrine of national self-determination promulgated by Woodrow Wilson at the end of the Second World War and embodied in the League of Nations; the former found its final expression in the fascist movements of the inter-war years (see Fascism). Thus nationalism continues to present us with two very different faces. On the one hand it stands for a people’s right to protect and develop their inherited cultures and to be politically independent in association with those they regard as their compatriots. On the other hand it stands for forcible indoctrination in the national culture and the promotion of national interests abroad at the expense of other peoples. Once again we see why philosophers have very often reacted ambivalently to nationalist ideas.

3 Problems of nationality

Nationalist ideas raise a number of important questions in ethics and political philosophy. This section addresses three. Do we owe special obligations to our compatriots? How can the idea of national self-determination be justified? How should we resolve disputes about borders, and in particular secessionist demands by national minorities?

The first question arises because the claim, common to all forms of nationalism, that we owe special loyalties to our compatriots, seems to collide directly with the idea that morality requires us to show an equal regard for every human being, without making distinctions. Most moral philosophers, especially utilitarians and Kantians, embrace the idea of ‘equal regard’, which may be labelled ethical universalism. We should weigh the interests of all human beings equally, or show each person equal respect regardless of their particular relationship to us. This points to a form of cosmopolitanism (see International relations, philosophy of §4). But many of these philosophers, recognizing how demanding and how far removed from ordinary moral ideas strict universalism is, have also tried to make room for particular loyalties, including national loyalties. They argue, for instance, that duties that are universal in scope may be discharged most effectively if each us takes responsibility for the welfare of a small number of others. Or they argue that members of particular communities may be regarded as contractually obliged to give one another special assistance, the justification for such contracts (or quasi-contracts) again being universal in form.

The weakness of these arguments is that they have difficulty showing why nations should be singled out as the groups to which special obligations are owed. If I am a utilitarian, for instance, why should I acknowledge a special responsibility to contribute to the welfare of the poorer members of my own national community when there are people much worse off in other countries? Even if my sympathies are presently biased towards those closest to me, do I not have a duty to correct this bias for the sake of maximizing overall utility? It seems that if we are to recognize national obligations, we have to abandon universalism as a complete picture of ethics and allow particular obligations to enter at ground level, so to speak. We need a picture which allows us to connect questions about personal identity - who we are, where we belong - with questions about our responsibilities to others (MacIntyre 1984).

Turning next to national self-determination, critics of nationalism such as Kedourie (1966) have argued that nationalist appeals to a national or popular will are fundamentally misguided, and that our concern should be with

the quality of government - whether it observes the rule of law and protects our rights, for instance - rather than with its source. If we are governed well by outsiders, we have no justified grounds for complaint. This challenge forces us to look more closely at the reasons for favouring self-determination, of which there are several.

One such reason has to do with our interest in protecting and fostering the common culture that provides us with the resources for a meaningful life. This is especially the case when the culture in question is the culture of what Margalit and Raz (1990) have called an ‘encompassing group’. The best guarantee that such cultures will not be destroyed or forcibly altered is to be governed by representatives who also participate in the national culture. Given the pressures currently exerted on national cultures by worldwide commercial forces, this argument has obvious force.

A second reason concerns the part played by nationality in fostering trust between the members of a political community. Where a shared national identity creates mutual trust, it becomes easier to agree on particular disputed issues - each side having more incentive to reach a compromise - and there is also a better chance of winning support for policies that aid one section of the community at the expense of others. Of course this argument can be turned on its head by those who favour a state with minimal responsibilities: if your aim is to disable the state from doing very much, you should prefer it to be multinational in character, so that each community will try to block policies that favour the others (this argument was advanced by Lord Acton (1907)). But those for whom social justice is an important value, and those who place a premium on achieving political agreement by democratic means, will favour political communities that are held together by national solidarity.

Finally we come to the problems posed for nationalist doctrines by disputed boundaries and demands for secession. If the peoples of the world were neatly divided into separate nations living on well-defined territories, the principle of national self-determination would be easy to apply. But in reality populations are very often interspersed in such a way that any territorial division will leave many people living under national governments with which they do not identify; and national identities, too, may be somewhat ambivalent. What are we to say about groups such as the Basques, the Québecois and the Scots, who appear to identify in part with larger nations but also have distinct identities of their own that they want to express politically?

Problems such as these have led many liberals to conclude that appeals to nationality cannot settle the question of where the borders of states should be drawn. We must be guided by other values: we should decide borders on the basis of individual consent, allowing any subcommunity to secede from the state by majority vote as long as it extends the same right to its own minority groups (Beran 1984); or we should permit secession when the seceding group can show that it is the victim of serious injustice or that it is threatened with cultural extinction (Buchanan 1981).

These responses may underestimate the versatility of nationalist principles, however. The solution prescribed by these principles will vary depending on the facts of each particular case. Where a state currently houses two or more distinct and well-defined national communities, the case for a peaceful divorce will be very strong. Where a small minority lacks a territorial base and is dispersed throughout a larger national community, the best solution may be to open up the existing national identity to that minority by removing or playing down divisive elements - for instance, by diminishing the role played by religion - so that in the longer term it will be able to integrate without annihilating its own culture. Where we find subcommunities nesting inside larger communities, as in the examples given above, national self-determination suggests devolving power to these subcommunities so that they are able to protect and express their own culture, without breaking up the state as such, since this continues to give expression to their wider identities and loyalties.

There will none the less be tragic cases in which no redrawing of borders or restructuring of political authority is able to give divided communities adequate protection and self-determination. Conflicts such as that created by the partition of Bosnia cannot be resolved by appeals to these principles. Such cases remind us that nationalism cannot by itself be a complete political philosophy. At the very least we need to add to it principles such as human rights, which set limits to what may be done to communities and individuals in the name of the nation.

Native American philosophy

Native American philosophies are multiple and multiply different, though with some palpable commonalities. Cosmologically, Native American thought posits phased differentiations of form from a primordial void. Form is fundamentally animate, and widespread metaphysical premises indicate a pervasive animism. The relationship between language and reality is grounded in the semiotic manipulation of animate forces. Encompassing force - like Siouan wakan *or Iroquoian* orenda *- is the originating source of human ontology and subjectivity, which are strongly characterized by ideas of consciousness and will. Mind is critically informed by transcendental experience (dreams, visions and so on) as well as by reason. Ethically, the harnessing of individual energies to specified social goals is discursively and dramatically prominent especially in ritual performance. Ethical principles are extended to non-human 'persons' (particularly animals and deific forms) who operate within the human moral compass. Native American reason emphasizes analogy (especially in Lévi-Strauss' interpretations) and aetiology, and there is a central concern with formal composition and decomposition. The latter is strongly evident in the ubiquitous philosopher-figure 'Trickster' - a subversive transgressor of constituted order.*

1 Background

Prior to 1492 Native North America included ten to fifteen million people, speaking 250 distinct languages (none written), belonging to more than twenty largely unrelated language families. There were upwards of 300 separate 'cultures' - that is, forms of life constitutively differentiated according to language, livelihood, social form and belief. Larger groupings into 'culture areas', united by geographic proximity, subsistence practices and customs, minimally include (with examples of named peoples in parentheses): Northeast Woodlands (Mohawk, Seneca, Pequot, Delaware), Southeast (Cherokee, Creek, Choctaw, Chickasaw), Plains (Lakota, Cheyenne, Comanche, Kiowa), Southwest (Hopi, Zuni, Navajo, Pima-Papago), Great Basin (Paiute, Shoshone, Washo, Ute), Plateau (Nez Perce, Klamath, Yakima, Kutenai), California (Yurok, Pomo, Yokuts, Maidu) Northwest Coast (Tlingit, Kwakiutl, Tsimshian, Nootka), Sub-Arctic (Koyukon, Beaver, Cree, Montagnais-Naskapi), and Arctic (numerous Eskimo/Inuit groups and Aleut).

While philosophical forms cannot be read from economic adaptation, certain limitations are imposed by population size and density, and ensuing social contexts. State-level societies, for example, seem prerequisite for higher mathematics and, correlatively, symbolic logic. Some North American number and calendrical systems were quite complex: the Pomo, who participated in a wide-ranging shell-disc currency, had a counting capacity up to 40,000; likewise, prehistoric Anasazi astronomical observations were notably fine-grained. But both mathematical and astronomical differentiation were significantly greater in the Classic Maya state, with its interlinked day- and year-counts, observatories and writing-system.

Each culture-area is characterized by ecosystems allowing particular modes of adaptation. Maize-beans-squash agriculture, the foundation of stratified states in Mesoamerica, occurred in the Northeast, Southeast and small areas of the Plains and Southwest; in these regions status differences distinguished ritual priest-leaders as the intellectual specialists. Elsewhere, dependence on hunting (Plains, Plateau, Sub-Arctic and Arctic), and wild plant collection (Great Basin, California and parts of the Southwest) are associated with smaller populations and more egalitarian societies; here, individual shamans ('medicine-men') are the philosophical experts. Interestingly, the fishing societies of the Northwest Coast produced fairly dense hierarchical communities that marked the metaphysical qualities of high-ranking individuals with titles, crests, masks and other insignia, all subject to contestation in elaborate ceremony (the 'potlatch').

Sociocultural diversity is accompanied by extensive historical differences. Archaeological remains attest to states in the Southeast - the 'Mississippian' - and the Southwest - 'Anasazi' and 'Hohokam'. These civilizations collapsed before 1492, though elements of the former persisted into the seventeenth century (especially with the Natchez), and elements of the latter are still found in Pueblo and Pima-Papago societies. European contact was devastating. Population declined massively (up to ninety per cent) from introduced diseases and genocidal wars. Today many languages are dead and numerous systems of thought are irretrievable. Yet in some areas indigenous culture remains strong; many Hopis and Navajos, for example, still speak their own languages, and some cultural forms are largely unaltered from pre-European times.

The corollary of a traumatic history is the erasure of records. There was little genuine interest in Native thought, peremptorily dismissed as ‘savage’ or ‘primitive’. The meditations of Montaigne, Locke or Rousseau on Native social and natural philosophy were largely oppositive projections of European conceptions onto people who typified the ‘state of nature’ - ornamented with frequently misconceived observations by explorers or missionaries (Lafitau’s *Moeurs des sauvages amériquains* (1724) is a partial early exception). Since the languages were oral, philosophical thought often did not survive unless translated and transcribed by chroniclers literate in a European language. Most early intellectually-oriented inquisitors were missionaries, whose epistemological intents were not neutral. Recorded occasions of genuine philosophical dialogue are sparse (those of turn-of-the-century physician James R. Walker with George Sword and other Lakota shamans are noteworthy). Even with sincere interest, interlocutors have typically had an insufficient grasp of notoriously complex linguistic forms for effective understanding. One of the few academic philosophers to undertake field research likens his dialogue with an elderly monolingual Navajo, translated by younger bilinguals, to ‘trying to talk to Plato with an Attican peasant as interpreter!’ (Ladd 1957: 201). In sum, the difficulties of knowing much genuine Native American philosophy are manifold, owing to its multiplicity and diversity, as well as to problems of translatability, both linguistic and social, compounded by historical circumstances.

2 Cosmology, metaphysics and ontology

For many Native American philosophies, a pervasive animism - denoted by Siouan *wakan*, Iroquoian *orenda*, Algonquian *manitou*, and Kwakiutl *nawalak* - is fundamental. This widespread idea posits, in all things and processes, an inherent vital force which has compulsive effects on events and conditions, may become attached to or the possession of individual ‘persons’ (not only human), and was the originating source of all phenomena. Iroquoian *orenda*, for example, is a:

> hypothetic principle…conceived to be immaterial, occult, impersonal, mysterious in mode of action, limited in function and efficiency, and not at all omnipotent, local and not omnipresent, and ever embodied or immanent in some object, although it was believed that it could be transferred, attracted, acquired, increased, suppressed, or enthralled by the orenda of occult, ritualistic formulas endowed with more potency.
>
> (Hewitt 1906: 147)

Likewise, Siouan *wakan* is ‘the animating force of the universe, the common denominator of its oneness’ (DeMallie 1987: 28); the totality of life-forces are *wakan tanka* (‘the great *wakan*’, popularly translated ‘Great Spirit’). Conceptually, *wakan* is typically characterized by its impenetrability, and in use has radiating synecdochic and metaphoric referents. But its multiplex significations are formally divided by shamans into sixteen hierarchical (four times four) aspects (see Figure 1). Each of these has particular powers of creation and transformation in the founding of the universe and its continual unfolding in human experience and practice.

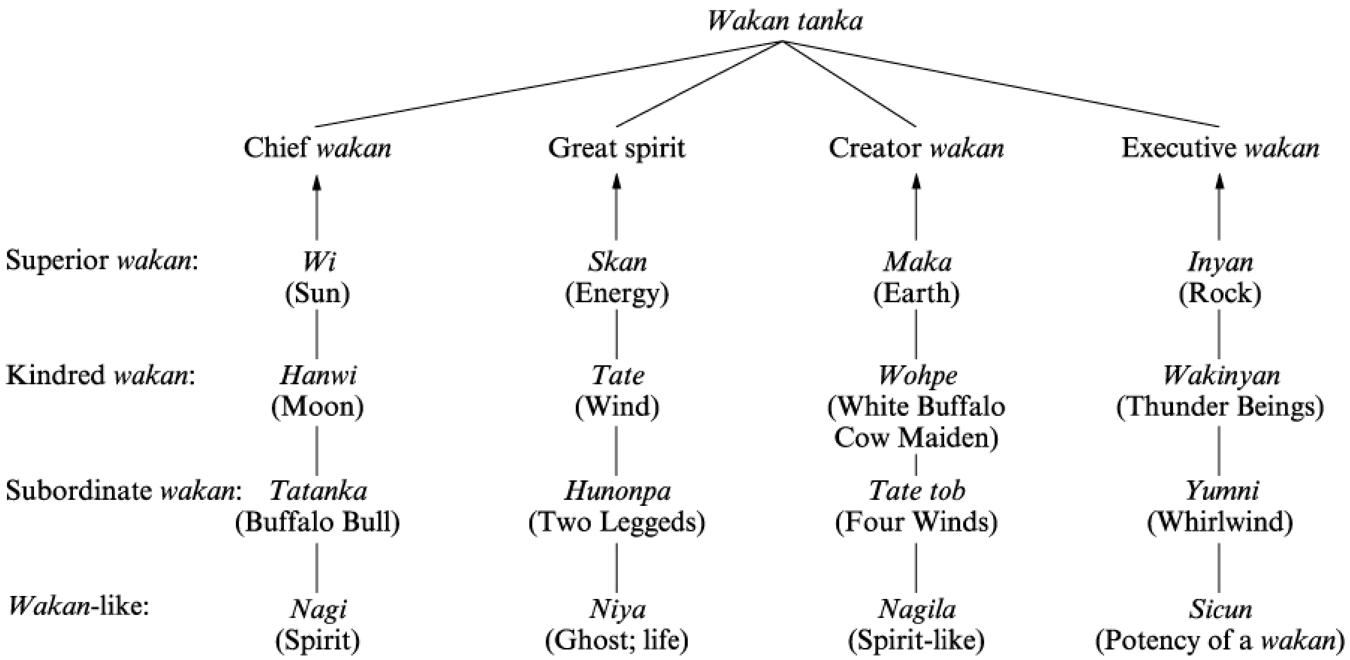

Figure 1. Tobtob kin, the four times four. (DeMallie and Lavenda 1977)

Here the abstraction of universal power converges with the constitution of human subjectivity. The Sioux person is animated at birth by three *wakan* elements given by *skan* ('Energy'): 'consciousness or will' (*sicun*, a guardian against evil); a ghost 'which comes from the stars'; and 'a spirit, evidently an immaterial but immortal reflection of the body'. 'After the death, the guardian escorts the spirit to the spirit world beyond the Milky Way; the guardian and the ghost return to the places from which *skan* originally got them' (DeMallie and Lavenda 1977: 157). These elements of ontogeny and ontology depict a human essence and matter particulate to universal totality. Simultaneously, a sense of phylogeny is central.

Narratives of origin vary, but many identify consecutive phases (for Zuni there are four, for Hopi three, for Tewa two). The natural and cultural world is progressively differentiated out of formlessness through active intervention by mystical forces (for Navajo these include coloured mists, swallows, and insects). At intermediate junctures, transformer-heroes appear in various guises, like Changing Woman and the monster-slayers, her twin sons by the Sun, for the Navajo and Apache. Gradually transformers produce sufficient order for humanoid forms, which evolve from primitivity to modernity (for example, Brightman 1990).

The Tewa (Pueblo) world was formed and ordered after the emergence of proto-humans from a primordial lake (Ortiz 1969). Various culture-heroes (including Mountain Lion the Hunt Chief, Summer Chief, Winter Chief, and six pairs of varicoloured sibling deities of the directions) were sent up by the originating Mothers, 'Blue-Corn Woman near to summer', and 'White-Corn Woman near to ice'. They harden the ground and order time, space, topography, seasonality, biology and social mores. The constructed world is bounded at its corners by four sacred mountains (with 'earth-navels' on the peaks); towards the centre these are successively linked to four flat-topped hills, four shrines at the village-margins, and finally four dance plazas in each Tewa village. The world ordering affects all aspects of Tewa existence and is dramatically reiterated in ritual; the culture heroes are impersonated, and all ritual trajectories - in speech, song, dance-movements and so on - insistently re-mark the tetradic structures, both temporally and spatially. In short, origin-narratives both explain the world and set the terms for human action within it.

Hopi metaphysics and ontology, evidenced in linguistic forms, emphasizes 'events', or 'eventings', that are objectively 'expressed mainly as outlines, colours, movements, and other perceptive reports', in contrast with the static substances, masses and entities foremost in European languages (Whorf 1956: 147). According to Whorf:

> Every language contains terms that have come to crystallize in themselves the basic postulates of an unformulated philosophy…. Such are our words 'reality, substance, matter, cause,' and… 'space, time, past, present, future.' Such a term in Hopi is the word most often translated 'hope' - *tunatya* - 'it is in the action of

> hoping, it hopes, it is hoped for, it thinks or is thought of with hope,'…. The verb *tunatya* contains in its idea of hope something of our words 'thought,' 'desire,' and 'cause,' which sometimes must be used to translate it. The word is really a term which crystallizes the Hopi philosophy of the universe in respect to its grand dualism of objective and subjective: it is the Hopi term for SUBJECTIVE. It refers to the state of the subjective, unmanifest, vital and causal aspect of the Cosmos, and the fermenting activity toward fruition and manifestation with which it seethes - an action of HOPING; i.e. mental-causal activity, which is forever pressing upon and into the manifested realm.
>
> (Whorf 1956: 61-2)

The difficulties of translating Native philosophies are partly descriptive. With some adjustments, Whorf's rendering of Hopi metaphysics calls to mind Heidegger's theory of being, particularly of existence as an emergence-into-presence (see Heidegger, M.).

Despite valuable criticism (for example, Malotki 1982), much of Whorf's analysis holds true. In Whiteley's (1988) research, one Hopi philosopher, Yoywayma, emphasized a triadic principle of idea, intention, and action - *tunatya*, *pasiwni*, *okiw antani*. In combination with *natwani*, an exteriorization of self, this triad suggests that - as for Husserl - intentionality and its worldly engagement is the defining feature of a conscious self (see Intentionality). *Tunatya*, explained with a characteristic horticultural metaphor, refers to a 'seed of thought' - the germ of an idea, we might say - that occurs in one's consciousness. *Pasiwni*, planning, means bringing together and setting into motion all the necessary technical and symbolic resources to germinate the seed and bring it to fructifying life. *Okiw antani*, 'let it be this way,' refers to proper mental attitude and is also a prayer that sanctifies the intention to control deific forces.

Pueblo thought discloses a common metaphysics (the 'Pueblo' Indians include the Hopi, Zuni, Tewa, Tiwa, Towa and Keres, all with entirely different languages but other cultural similarities):

> The general Pueblo conception of causality is that everything - animate and inanimate - counts and everything has its place in the cosmos. All things are thought to have two aspects, essence and matter. Thus everything in the cosmos is believed to be knowable and, being knowable, controllable. Effective control comes only from letter-perfect attention to detail and correct performance, thus the Pueblo emphasis on formulas, ritual, and repetition revealed in ritual drama. Among human beings, the primary causal factors are mental and psychological states; if these are harmonious, the supernaturals will dispense what is asked and expected of them. If they are not, untoward consequences will follow just as quickly, because within this relentlessly interconnected universal whole the part can affect the whole, just as like can come from like. Men, animals, plants and spirits are intertransposable in a seemingly unbroken chain of being.
>
> (Ortiz 1972: 143)

In Navajo metaphysics, causality and consciousness are linked through speech. Speech, especially in ritual, has causal power, simultaneously *doing* what it says: 'Ritual language does not describe how things are, it determines how they will be. Ritual language…disperses evil, reverses disorder, neutralizes pain, over-comes fear, eliminates illness, relieves anxiety, and restores order, health, and well-being'. Ritual speech derives from foundational knowledge of which reality itself is composed. In Navajo creation narratives:

> language is the means by which form is projected onto substance…. The symbol was not created as a means of representing reality; on the contrary, reality was created or transformed as a manifestation of symbolic form. *In the Navajo view of the world, language is not a mirror of reality; reality is a mirror of language*.
>
> (Witherspoon 1977: 34, emphasis in original)

3 Being and mind

The (Iroquoian) Huron believed in a soul both 'divisible and physical' with terms for the divisible parts. One part, *,aata*, is equated with the body, and with the body's life-force, but also with aspects of 'the self', particularly in moral interrelationship with other selves, in emotions and in personality. It also operates conjunctively, in an overall conception that is fundamentally dualistic:

> One major Huron conception of the soul, that of the perceptive or sensitive-animating one, is linked and is

> comprised of the emotive soul, *eiachia* or heart…, the general body-soul, *,aata*, and the general life-soul, *onnhek8i*. The second Huron conception, the rational or intellectual free soul, combined the intellectual soul, *,andi,onra* (mind), and the free soul, oki.
>
> (Pomedli 1991: 60)

The intellectual soul is the means of thought. In European philosophy, thinking is generally depicted as a process in which mind absorbs sensory impressions from external reality and then deliberates internally with the abstracted residue:

> Hurons, however, emphasize a more extrinsic method of thinking. For them, the mind, in the process of thinking, transports itself or is transported into the object or event in question…. Instead of the mind using its power to assimilate, it rather has the power to move into an object, enrich it, name it, make it meaningful, and empower it. The object or event remains out there, nevertheless, but is now changed and made similar to the mind because of the free-moving thinking process…. While for Europeans thinking involves the conscious and deliberative, that is, discursive activities, for Hurons it focuses on the imaginative and intuitive, that is, excursive activities.
>
> (Pomedli 1991: 65-8)

In conscious thought and in dreams there is an internal dialogue - an ‘immanent intersubjectivity’ - among Huron soul forms. A conception of multiple, particularly dual, souls (where one - the free soul or psyche - is detachable from the animate body) is widespread throughout North America.

Li’maqsti, ‘mind’, among the Nuu-cha-nulth (or Nootka) of the Northwest Coast, is conceptualized as a column of ten connected spiritual homunculi resident in the spinal cord. *Li’maqsti* incorporates ‘reason’ and ‘will’ and serves as a sort of transducer between sensation, mentation and action, between ‘internal and external states’. The realization of action from intention involves a colloquy:

> Each of the [ten connected] persons is an individual…and each is capable of autonomous thought. A man acts, in effect, by majority rule. If the ten persons are in complete agreement he knows just what to do; if they are in balanced disagreement, then he is incapable of acting at all.
>
> (Golla 1988: 4)

Concepts of mind emerge also in the widely remarked Native attention to dreams. Iroquois dream theory is ‘basically psychoanalytic’:

> They recognized conscious and unconscious parts of the mind…. [They made] the distinction between the manifest and the latent content of dreams and employed what sounds like the technique of free association to uncover the latent meaning. And they considered that the best method for the relief of psychic and psychosomatic distresses was to give the repressed desire satisfaction, either directly or symbolically.
>
> (Wallace 1969: 63)

Dream theories vary, but there are numerous echoes of Iroquois views (for example, Lincoln 1935), especially with regard to dreams as guides for conscious action. For the sub-Arctic Cree:

> Dream images may be understood as prophetic, as literal or symbolically disguised representations of future states of affairs. Memories of the dream are then retained by the waking self, providing foreknowledge of future occurrences….
>
> [But] Crees say that dream events may *determine* the occurrence of like events - their worldly simulacra - that have not yet happened but that will transpire in waking life only as a result of their having initially been dreamed. The dreamer…[further] conceives him or herself as capable of influencing worldly outcomes by choosing certain courses of action in the anticipatory dream.
>
> (Brightman 1993: 97-9)

In other sub-Arctic hunting societies, dreams may link a hunter’s psyche with that of an individual prey animal, or with a master-soul of the species, who guides the hunter to a waking bodily form as part of a reciprocal life-death compact between human beings and game animals from originary times. But in all cases, interpretive criticism and

failure are centrally acknowledged, belying an inference of naive mysticism.

In some cultures, a *totem* (an Ojibwa word from the Great Lakes - far from the misnamed ‘totem poles’ of the Northwest Coast), or guardian-spirit, watches over a person’s life. It may be appointed at birth or acquired in a ‘vision-quest’, especially at puberty. The widespread vision-quest, for both sexes, is a socially sanctioned will-to-power, involving fasts on mountain tops or other secluded spots deemed powerful, where through privation the individual seeks a transcendent vision, which, though more intense, is like ordinary dreaming in its informing of conscious action. If successful, a spirit-animal or deity representative appears, and conveys a personal power that may subsequently be invoked at will.

4 Ethics

Major visions were used to guide community actions and were ritually enacted in collective performance. The mutual dependence of self and society is also strikingly illustrated in the Plains Sun Dance. Individual men may elect to undergo extreme physical pain by piercing muscles with rawhide thongs attached to a pole representing the *axis mundi*, and pulling away until the flesh is broken or they lose consciousness - an act of self-sacrifice for the spiritual benefit of the whole community.

The individuated yet relational self is often associated with concrete ethical manifestations in objective reality. For the Hopi, ethical values prescribe modesty, self-effacement, interpersonal and environmental responsibility, industry, courtesy, circumspection, and humility. *Natwani*, the exterior reflection of one’s performance, may refer to crops, children or other fruits of personal effort; if these turn out well, they accrue to the individual’s virtue as ‘*hopi*’ (an ethical term in itself, encapsulating the values mentioned). Ethically composed and judged selves in intersubjective relationship engender and reproduce moral community. After detailed field study, philosopher Richard Brandt (1954: 72) concluded that, ‘it is doubtful whether there is any evidence for ethical attitudes or remorse in Western society which cannot be matched among the Hopi’.

Ladd (1957: 212-13) interprets Navajo ethics as ‘rational’ (especially in terms of moral justification for action), ‘prudential’ (particularly regarding the individual’s welfare), ‘egoistic’ (promoting individual satisfaction), and ‘utilitarian’ (aimed at happiness for all) (see Egoism and Altruism; Utilitarianism). The central goal is *Są’ah Naagháii Bik’eh Hózho* which refers, *inter alia*, to the continuous reproduction of beauty, health, long-life and happiness for self and community (Witherspoon 1977: 13-46).

In many Native societies, high value is placed on both individual autonomy and harmonious cooperation. Coercion is rare and social adherence depends on individual assent. Conformism is perhaps most strongly emphasized in Pueblo values, although the standard Hopi phrase ‘*pi um ‘i’*’ (‘it is up to you’), stresses individual choice. Individual autonomy is especially strong in northern hunting societies, but here too is accompanied by a powerful sense of mutual reliance. While there are exceptions (as in the institution of partial slavery in Northwest Coast societies), this conjoint ethos of individual autonomy and interpersonal responsibility is so widespread it represents a deep-seated moral choice in the Native American *conscience collective*, and an implicit rejection of the Enlightenment social contract, conceived as the surrender of ‘natural rights’ to a sovereign, from which much contemporary Western social and political philosophy stems.

Ethical principles are also extended to non-human ‘persons’, particularly game-animals. According to Penobscot (Eastern Algonquians):

> The animals know beforehand when they are to be slain, when their spirits have been overcome by the hunter’s personal power or magic. They exact also a certain respect, which is shown to them in different ways, through generally by the proper treatment of their remains after they have been killed for their flesh or skins. If this respect is not accorded to them, the animals refuse to be killed or their souls may not be reborn.
>
> (Speck 1935: 32-3)

How, though, do these beliefs differ from mere anthropomorphism? Rock Crees ‘ascribe animateness, self-awareness, intelligence, and sometimes covert humanoid characteristics to many non-human beings and objects’. But they simultaneously depend on a detailed pragmatic knowledge that emphasizes human-animal differences that are ‘constitutive of and endlessly objectified in the human practice of killing and eating animals’ (Brightman 1993: 77, 179). The dualism of ethical consubstantiation and pragmatic differentiation reflects the

central metaphysical dichotomy between ‘matter and essence’ noted above for Pueblo world-view. It is the essential forms of nature that are included within the ethical sphere of ‘persons’; the material forms are objects of pragmatic interaction.

5 Epistemology and reason

Native knowledge systems are grounded in the metaphysical and ontological principles so far described. In Hopi, knowledge as an abstraction is denoted by *navoti*, the closest equivalent to ‘philosophy’, but also implying such European paradigms as *scientia*, theology, epistemology, psychology, hermeneutics and with a determinist cast in which events are fore-ordained (with a causal nexus in mystical forces). What is known through *navoti* may, by the same token, be acted upon. *Navoti*, especially in ritual use, is, like Navajo speech, causative: a *pouvoir/savoir* addressed to supernatural causes attributed with conscious animate force.

Many Native American societies denominate social units by natural species and elements: the Hopi have more than thirty matrilineal clans, including Bear, Spider, Greasewood, Badger, Butterfly, Sun, Parrot and Eagle. Lévi-Strauss has produced a penetrating analysis of this ‘totemic logic’, which, he argues, is fundamentally relational:

> The homology they [totemic institutions] evoke is not between social groups and natural species but between the differences which manifest themselves on the level of groups on the one hand and on that of species on the other. They are thus based on the postulate of a homology between *two systems of differences*, one of which occurs in nature and the other in culture.
>
> (Lévi-Strauss 1966: 115)

Natural classes are thus ‘good to think’, that is, as metaphorical vehicles for conceptual differentiation - behaviourally, epistemologically and socially. The inferred mode of thought is fundamentally analogical, operating with a ‘system of concepts embedded in images’ that serve to build ‘mental structures that facilitate an understanding of the world in as much as they resemble it’ (Lévi-Strauss 1966: 264, 263).

Lévi-Strauss extrapolates Native American systems of thought from mythological narratives (especially), social forms, arts and architecture. In myth, embedded codes of meaning operate both episodically (‘syntagmatically’) and thematically (‘paradigmatically’). The narratives unfold via a series of binary oppositions ranged along multiple intersecting planes, including geography, economy, sociology and cosmology - ‘each one of these levels together with the symbolism proper to it, being seen as a transformation of an underlying logical structure common to all of them’ (Lévi-Strauss 1968: 1). The oppositions derive from contradictory principles in social experience. Myths, then, seek to ‘resolve’ paradoxes and contradictions, which are in fact irresolvable, by correlating oppositions from the different planes and postulating syntheses. In a Tsimshian (Northwest Coast) story, for example, Asdiwal, a supernatural transformer-hero, is the figure of attempted synthesis between (*inter alia*): endogamy versus exogamy, famine versus plenty, salmon versus candlefish, mountain-hunting versus sea-hunting, female versus male, movement versus immobility, patrilocal residence versus matrilineal descent, downstream versus upstream, mother versus daughter, and heaven versus earth. The mythic interplay of these oppositions configures the attempt epistemologically to overcome their individual contradictions. This ‘fundamental notion of dualism in a perpetual state of disequilibrium’ Lévi-Strauss sees as pervading Native American systems of thought:

> In Amerindian thought a sort of philosophical bias seems to make it necessary for things in any sector of the cosmos or society to not remain in their initial state and for an unstable dualism to always yield another unstable dualism, regardless of the level on which it might be apprehended.
>
> (Lévi-Strauss 1995: 231)

Lévi-Strauss’ position is persuasive. Dual forms of social and conceptual organization are common, from the Red-White social binaries of the Creek confederacy to paired masks of the Kwakiutl and Salish, the Winter-Summer Tewa moieties, diametric town-plans of the Winnebago and oppositive species in Keresan emergence myths. Ortiz (1969) confirms a pervasive dualism in Tewa culture, but challenges its supposed insolubility. Tewa social oppositions are resolved cyclically through temporal alternations where one or the other of the Summer-Winter pair has successive executive authority. Herein lies an indication of the limits of

Lévi-Strauss' interpretation of Native thought, removed as it is from first-hand empirical inquiry.

The Hegelian and Kantian foundations of Lévi-Strauss' approach are clear: the former in his dialectical reason and the latter with his tacit reliance on a transcendental subject. Both principles are, then, inferred as key components of Native American thought *sui generis*. But if a major logical process in Native thought systems is autogenously dialectical, this operates largely without the conscious intervention of any Native thinker: Lévi-Strauss (1970) holds that mythological thematic operators (oppositions, or figures like Asdiwal himself) *think themselves* out through individual minds and tellings rather than vice versa.

While of great heuristic value, Lévi-Strauss' semiotic reductions result in an abstract logical and aesthetic formalism, where the endless interplay of binary oppositions becomes a hall of mirrors (see Lévi-Strauss, C.). In use in Native discourse, species names and denotations are both literal and often multiply symbolic. A re-analysis of Hidatsa names with Frege's notions of sense and reference opens out the understanding of Native signification considerably further (Barnes 1980). Similarly, for the Hopi, who continue to gather fledgling eagles each May, species meanings are more than mere logical abstractions. Eagles are 'persons' from a Hopi point of view and reincarnate clan ancestors. Eagles are, then, good to think, but they are also sentient spirits who are good to be with and who mediate prayers to deity, in a cosmos saturated with sentient subjects rather than rote mechanistic forms.

Particularly for shamans, narratives of personal relationship with animals and elements are frequent. Eskimo shamans, for example, were thought capable of detaching part of their selves from their bodies and visiting the under-sea homes of deities. Some shamanic initiations among Tikigaq Eskimos involve metamorphosis into animal forms, like whales. Yet indigenous scepticism of both particular claims and general principles is clearly apparent (Lowenstein 1992: 91, 78-84). A well-known example of scepticism involves a Kwakiutl man, Quesalid, who doubts shamanic claims. He proceeds, as an empirical test, to apprentice himself, and goes about exposing the fraud of others. But he also becomes a highly successful curer himself. Quesalid's apprenticeship does not entail a transition to uncritical belief, but rather a comprehension of the social and psychological contexts in which shamanic techniques productively operate.

If in origin narratives a central concern is ordering by categorial differentiation, and if ritual's key intent is to exert control over a deterministic world, these are always accompanied by a simultaneous indeterminacy principle. In myths, this is instantiated by Trickster, and in rituals, by formal clowning and games. Trickster resists structure, is instinctual and without ethics or conscience. He/she/it is (willy-nilly) a major creative force in some instances, in others ancillary to more prominent creators. But everywhere, Trickster - embodied as Coyote, Hare or Raven, or a bodiless figure of metamorphosis - represents the chance element, the subversion and transgression of order, and, through selfish desire, vanity, lust, greed and gluttony, is both inverse ethical exemplar and an avenue of comic release and communal therapy. Trickster is a protohuman cheerleader for flawed humanity, who mocks the claims to righteousness of gods or pious humans. But Trickster is, reflexively, a satire of creatural vanity, displaying an ironic, ambivalent sense of the human condition marked by a continual failure to live up to ideals, and he/she/it ostensively defines the provisionality of all established forms:

> The symbol which Trickster embodies is not a static one. It contains within itself the promise of differentiation, the promise of god and man…. He represents not only the undifferentiated and distant past, but likewise the undifferentiated present within every individual. This constitutes his universal and persistent attraction. And so he became and remained everything to every man - god, animal, human being, hero, buffoon, he who was before good and evil, denier, affirmer, destroyer and creator. If we laugh at him, he grins at us. What happens to him happens to us.
>
> (Radin 1956: 168-9)

In Winnebago narratives, *wadjunkaga*, 'the tricky one', passes through a series of episodes in a developmental cycle; along the way, his left and right hands fight and cause serious injury to each other, he wounds his own (personified) anus for failing to guard a brace of ducks, eats his own intestines, punishes a chipmunk with his penis that gets chewed off in return, changes sex to marry a chief's son, claims to be a war chief but systematically violates all the taboos, and so on. The cycle depicts a journey from a formless, childlike id ruled by immediate sensory and intellectual gratification, in which everything is misconceived - biology, cosmology, social roles, sexuality, mortality and morality - towards biological, social, and psychological definition. In a conscious

mythological world where other creatures comment adversely on his exploits, Trickster the protohuman blunders about, asocial and isolated, largely unconscious of the effects of his actions. Logically and cosmologically, trickster is antithesis, subversion, imbalance.

Mixed-blood Anishinabe philosopher Gerald Vizenor extends Trickster into his own work, showing further how it operates as a sign. He writes both *of* and *as* Trickster against the reification of social-scientific analysis:

> Tricksters, the wild ironies of survivance, transformation, natural reason, and liberation in stories, are marooned as obscure moral simulations in translations…. *The trickster is a language game*, a counter causal liberation of the mind.
>
> Trickster is androgynous, a comic healer and liberator in literature: the whole figuration that ties the unconscious to social experience. The trickster sign is communal, an erotic shimmer in oral traditions; the narrative voices are *holotropes* [total figures] in a discourse.
>
> (Vizenor 1994: 76-7, 89, first emphasis added)

Trickster frees from structure, a semiotic sign forever darting in and out of established meaning and reference (including its own), and a Native counterpart to postmodernism's free play of signification and subversion of master-narratives (see Postmodernism).

Hopi clowns play out the same philosophical drama in a two-day ceremony. To begin with, clowns, *tsutskut* ('the pointed ones', after a feature of their costume, but also 'those who are making a point' - the double meaning also works in Hopi) specifically symbolize undifferentiated consciousness, humanity in a childlike state innocent of understanding, virtue or evil. During a line-dance performance by kachinas (masked representations of spirits, which here embody pure essences of the differentiated cosmos) unmasked clowns appear in counterpoint, lampooning everything sacred or normative in Hopi values, and following Trickster's trajectory of semi-successful category learning by the end of the ceremony. At a critical moment, under threat of death by moralizing warrior kachinas, they agree to try order, and to demonstrate this they imitate the kachinas in the line-dance. After a few tries, however, they fall apart, hopelessly incapable.

Several key themes of Native American philosophy are conjoined in this performance. When they first appear in the plaza, clowns are the children of the Sun arriving in a formless void (initially they do not notice the kachinas) where they start iconically building the world and their place within it, though with frequent reversals of contemporary significations. Their transgressions are comically played out for the Hopi audience, which then reflexively inspects the world's categories and codes, re-notes their arbitrariness and provisionality, delights in the cathartic subversion of the intending human self, its acts and foibles, and is reminded of the virtue and vitality of created natural and social order. This play of order and disorder dialectically deconstructs the human condition - cosmologically, metaphysically, ontologically, biologically, ethically and epistemologically. Trickster, in a word, is the philosopher.

Carroll, Cambridge, MA: MIT Press.(Selected writings of Benjamin Lee Whorf who, with Edward Sapir, is the key figure in linguistic relativism, which suggests that differences in thought are systemically conditioned by language differences, resulting in incommensurable phenomenologies: this anthology contains Whorf's central arguments, with specific foci on Hopi language and thought.)

Witherspoon, G. (1977) *Language and Art in the Navajo Universe*, Ann Arbor, MI: University of Michigan Press. (A linguistically and culturally well-informed philosophical analysis of Navajo metaphysics and epistemology.)

Nativism

Traditional empiricism claims that the mind is initially equipped only with the capacity for experience and the mechanisms that make it possible for us to learn from experience. Nativists have argued that this is not enough, and that our innate endowment must be far richer, including information, ideas, beliefs, perhaps even knowledge.

Empiricism held the advantage until recently, partly because of a misidentification of nativism with rationalism. Rationalists such as Descartes and Leibniz thought nativism would explain how a priori knowledge of necessary truths is possible. However, the fact that something is innate does not establish that it is true, let alone that it is necessary or a priori.

More recently, nativism has been reanimated by Chomsky's claims that children must have innate language-specific information that mediates acquisition of their native tongue. He argues that, given standard empiricist learning procedures, the linguistic data available to a child underdetermines the grammar on which they converge at a very young age, with relatively little effort or instruction.

The successes in linguistics have led to fruitful research on nativism in other domains of human knowledge: for example, arithmetic, the nature of physical objects, features of persons, and possession of concepts generally.

1 Nativism and empiricism

The fact that we human beings understand the world to the extent that we do depends on two factors: our inherent nature as thinkers, and the specific course of our experience. One of the great oppositions in the history of philosophy has centred on the relative contributions of each of these factors. Empiricists hold that experience provides all the raw materials out of which knowledge and understanding is fashioned: the mind is often compared to a *tabula rasa* (blank slate) initially equipped only with the capacity for experience and the ability to build upon and learn from past experience. Nativists have argued that this is not enough, and that our innate endowment is richer than the empiricist allows (see Empiricism).

Although nativists agree that empiricism is mistaken, they differ widely over the sorts of things that are innate - for example, ideas, principles, knowledge, dispositions, biases, representations, concepts, strategies, theories - as well as about the domains in which innateness must be invoked: Leibniz argued for it primarily for logic and mathematics; Plato for all *genuine* knowledge (see Innate knowledge). The matter is further complicated by the fact that empiricists themselves must inevitably incorporate some nativist elements in their own theorizing. At the very least, the ability to experience the world and the basic machinery that makes building on such experience possible must be innate and not learned. But empiricists typically argue that such commitments are innocuous, not specific to any domain, and (especially in recent empiricism) do not involve the elaborate mental machinery that nativists standardly posit.

Perhaps what unifies all nativist positions is a reliance on what Noam Chomsky has called the 'poverty of the stimulus' argument scheme. Nativists point to some discrepancy between our experience (the stimulus) and the knowledge (or ideas, concepts, principles, and so on) that we eventually come to have, and argue that this discrepancy cannot be made up by invoking the sorts of simple learning mechanisms posited by empiricists - association and conditioning, for example. It follows that we must be contributing something substantial 'from our side' in the construction of knowledge, and this is what is innate.

The earliest nativist argument is in Plato's *Meno*, where Socrates' questioning enables Meno's uneducated slave to discover 'for himself' a theorem of geometry (*Meno* 80a-86c). Socrates argues that his questions have 'reminded' the slave of what he knew innately. Indeed, for Socrates, all knowledge (properly construed) is acquired by recollecting what is innate in the soul from an earlier existence (the doctrine of anamnesis - see Plato §11). In the *Phaedo* (73c-78b) is a related argument: Socrates claims that the notion of equality involved in perceiving a pair of sticks as equal could not have its source in experience and therefore must be innate.

A similar pattern of argument pervades seventeenth-century rationalist defences of innateness. Descartes and Leibniz argue that our knowledge of the necessary truths of mathematics seems to be justifiable a priori, or 'independently of experience': mathematicians do not need to perform experiments to test whether $2+2=4$.

They thought that nativism would explain how such knowledge was possible (see Rationalism).

However, this is a dubious explanatory strategy. Nativism is a claim about the *origins* of knowledge; *rationalism* is a claim about its *justification*. The fact that something is innate does not establish that it is true, let alone that it is necessary or a priori: someone might be born believing that space is Euclidean or that smiling faces are to be trusted, neither of which is even true.

Empiricists attacked nativism in two ways. One approach challenged the legitimacy of nativism as a plank in a theory of knowledge. Locke, for instance, argued that nativism reduces either to the nonsensical view that we are, in an everyday sense of the term, literally born knowing things, or to the trivially true and empty view that we have an innate capacity to think and to discover truths. Of course, he then needed an account of how knowledge was possible. He and later empiricists offered what may be termed 'adequacy of the stimulus' counter-arguments (see Behaviourism, methodological and scientific; Hume, D.; Logical positivism; Quine, W.V.). They constructed theories of the mechanisms of inductive inference, of concept formation and so on, and applied them to specific cases (for example, our idea of infinity, our knowledge of general causal laws) to argue that such mechanisms can indeed generate our knowledge given the raw materials of experience. This philosophical effort was in the twentieth century reinforced by the concurrent growth of an independent science of associationist-behaviourist psychology, as well as, more recently, connectionist models of cognitive processing, all based on empiricist principles (see Connectionism).

2 Linguistic nativism

The dominant philosophical view for most of the twentieth century was that the empiricists had won. But all this changed in the 1960s, due in large measure to Noam Chomsky's arguments that empirical research in linguistics vindicated the rationalist innateness doctrine (as well as its attendant mentalism) over its empiricist counterpart (see Chomsky, N.; Language, innateness of).

Chomsky's ground-breaking work has been largely responsible for the development of linguistics as a deeply theoretical empirical science. He argued that language users have an internal representation of a set of rules that relate utterances to meaning and thereby enable them to understand and produce sentences of their language. These rules constitute the grammar of the particular language in question, and determine which patterns constitute well-formed sentences of the language and which do not. The central finding of modern linguistics is that the grammatical rules that govern natural languages are surprisingly complex and non-obvious: they cannot be known by mere casual reflection on one's own linguistic practice, and bear only a remote connection to the traditional schoolbook grammars. Indeed, their specification seems to require a very sophisticated technical apparatus, and what they allow and disallow cannot be accounted for in terms of any generic requirements on communication (see Syntax).

Furthermore, if we compare the linguistic data available to the child to the grammar of the specific language the child comes to master, we see that the data severely underdetermines the grammatical rules. There are many alternative rules that could claim as strong inductive support from the child's data as the rules children actually master. Nevertheless, all normal children who learn a language arrive at the same set of rules at a very young age, with relatively little effort, and with little (if any) relevant explicit instruction. Despite disagreement within linguistics about how to specify the particulars of this picture, the preponderant view of the evidence as it now stands is that such a nativist approach is unavoidable.

Philosophers committed to empiricism have responded to Chomsky's linguistic nativism in a variety of ways. Some claim that knowing a language is not a matter of knowing *that*, but rather knowing *how*: one can know how to walk without knowing the specific physical principles that govern walking. Empiricists can then freely grant that there is innate know-how without having to claim there are any innate ideas. Some, echoing Locke, have challenged innate 'Universal Grammar' because of the remoteness of such rules from consciousness (see Consciousness §7; Knowledge, tacit; Unconscious mental states).

Still others have claimed that the most that Chomsky-style nativist arguments show is that speakers of a language have various innate *beliefs*, but no *knowledge*; for, after all, the neonate's beliefs are not *justified* (see Knowledge, concept of). Finally, Hilary Putnam has argued that Chomsky's conclusions are premature because we still have a poor understanding of the general inductive principles that make learning from experience possible (see Inductive

inference). Until and unless we understand how induction works, we will be in no position to argue that it cannot account for the acquisition of a grammar. Notice, however, that at the very least, this argument concedes the force of the nativist evidence and admits that the long-dominant empiricist paradigm remains underdeveloped.

A more forceful but speculative nativist line of response would challenge the whole notion of general inductive principles. The idea would be that, for any domain of knowledge, we either have special-purpose innate structures that mediate its acquisition, or else we adapt one of the special-purpose structures already in place and refit it for a new domain (for example, applying innate combat strategies to chess). Such a hypothesis does posit some sort of general purpose 'refitting' function, but it clearly has a central nativist core.

3 Nativism in philosophy and empirical science

The success of the Chomskian paradigm in linguistics has strongly influenced research in cognitive development, and there are a number of empirical research programmes aimed at showing that, contrary to the empiricist and Piagetian paradigms, different domains of human knowledge rest on domain-specific innate bases (see Cognitive development; Cognition, infant; Mind, child's theory of; Piaget, J.).

For example, recent findings suggest that 5-month-olds already have some expectations about the results of simple arithmetic operations, manifesting surprise (measured in looking time) at scenes displaying one object where two were to be expected, as a result of either addition or subtraction of objects by hands disappearing behind screens (Wynn 1992). Similar work suggests that the infant's notion of what constitutes a single physical object and certain elementary physical principles may be innately understood (Kelman and Spelke 1983; Baillargeon 1987). There seem to be innate ideas about specific kinds of objects: newborn babies (even less than 10 minutes old!) will look longer at a schematic of a normal human face than at a face with scrambled features (see Morton and Johnson 1991).

Of course, showing that a concept is already present in a 6- or even a 4-month-old does not show that it is innate (although it is hard to extend such scepticism to an infant only 10 minutes old). But as the evidence mounts for earlier and earlier concepts and knowledge, the burden of argument shifts to the anti-nativist camps (which generally predict later onset).

An important philosophical development associated with the Chomskian revolution is Jerry Fodor's radical concept-nativism, which also has roots in Plato and Descartes. Fodor (1981) argues that no empiricist theory of concept learning is viable; all our concepts (to a first approximation) are therefore innate. He points out that empiricist theories implicitly assume that that there is a set of unlearned primitive concepts, typically sensory ones such as hard or red, and propose 'reducing' all other concepts to these (see Concepts §6). However, he argues, such 'reductionist' efforts have been notorious failures, as leading empiricists including Quine (1953) and Putnam (1965) have conceded. Moreover, recent experimental studies indicate that what the empiricist would take to be complex concepts are not represented in the mind as complex mental representations. So, Fodor concludes, these too must be primitive, and therefore innate. Needless to say, these arguments have stirred substantial controversy, both about the resources of reduction, and the interpretation of these latter experimental studies.

In place of the empiricist picture of concepts learned from experience, Fodor offers a triggering model that is familiar in cognitive ethology. Ethologists have discovered that for some bird species, the young bird has only to hear some song or other for it to begin singing its species-characteristic song (see Learning §2). This is plainly not a matter of learning from experience; experience is more of a release or trigger. Fodor's suggestion is that concepts - like some birds' song - are innate but dormant, waiting patiently for the right experience to trigger them and bring them into cognitive play. This would doubtless be music to Socrates' ears.

Natural deduction, tableau and sequent systems

Different presentations of the principles of logic reflect different approaches to the subject itself. The three kinds of system discussed here treat as fundamental not logical truth, but consequence, the relation holding between the premises and conclusion of a valid argument. They are, however, inspired by different conceptions of this relation. Natural deduction rules are intended to formalize the way in which mathematicians actually reason in their proofs. Tableau systems reflect the semantic conception of consequence; their rules may be interpreted as the systematic search for a counterexample to an argument. Finally, sequent calculi were developed for the sake of their metamathematical properties.

All three systems employ rules rather than axioms. Each logical constant is governed by a pair of rules which do not involve the other constants and are, in some sense, inverse. Take the implication operator '$\rightarrow$', for example. In natural deduction, there is an introduction rule for '$\rightarrow$' which gives a sufficient condition for inferring an implication, and an elimination rule which gives the strongest conclusion that can be inferred from a premise having the form of an implication. Tableau systems contain a rule which gives a sufficient condition for an implication to be true, and another which gives a sufficient condition for it to be false. A sequent is an array $\Gamma \vdash \Delta$, where Γ and Δ are lists (or sets) of formulas. Sequent calculi have rules for introducing implication on the left of the '$\vdash$' symbol and on the right.

The construction of derivations or tableaus in these systems is often more concise and intuitive than in an axiomatic one, and versions of all three have found their way into introductory logic texts. Furthermore, every natural deduction or sequent derivation can be made more direct by transforming it into a 'normal form'. In the case of the sequent calculus, this result is known as the cut-elimination theorem. It has been applied extensively in metamathematics, most famously to obtain consistency proofs. The semantic inspiration for the rules of tableau construction suggests a very perspicuous proof of classical completeness, one which can also be adapted to the sequent calculus. The introduction and elimination rules of natural deduction are intuitionistically valid and have suggested an alternative semantics based on a conception of meaning as use. The idea is that the meaning of each logical constant is exhausted by its inferential behaviour and can therefore be characterized by its introduction and elimination rules.

Although the discussion below focuses on intuitionistic and classical first-order logic, various other logics have also been formulated as sequent, natural deduction and even tableau systems: modal logics, for example, relevance logic, infinitary and higher-order logics. There is a gain in understanding the role of the logical constants which comes from formulating introduction and elimination (or left and right) rules for them. Some authors have even suggested that one must be able to do so for an operator to count as logical.

1 Natural deduction

Systems of natural deduction were first devised in the late 1920s by Gerhard Gentzen (1935), a student of Hilbert's, and, independently, by Stanislaw Jaśkowski. Their derivations formalize proofs from assumptions and are most conveniently represented as tree-like structures with the conclusion at the root and an assumption at the top of each branch. Assumptions may be discharged by the application of a rule in the course of the derivation, and the conclusion will depend only on the undischarged assumptions. Here is one formulation of the introduction and elimination rules for the usual logical operators:

(1) $\dfrac{A \quad B}{A \wedge B}$ (2) (a) $\dfrac{A \wedge B}{A}$

(b) $\dfrac{A \wedge B}{B}$

(3) (a) $\dfrac{A}{A \vee B}$ (4) $\dfrac{A \vee B \quad \begin{matrix}[A] \\ C\end{matrix} \quad \begin{matrix}[B] \\ C\end{matrix}}{C}$

(b) $\dfrac{B}{A \vee B}$

(5) $\dfrac{\begin{matrix}[A] \\ B\end{matrix}}{A \rightarrow B}$ (6) $\dfrac{A \quad A \rightarrow B}{B}$

(7) $\dfrac{\begin{matrix}[A] \\ \bot\end{matrix}}{\neg A}$ (8) $\dfrac{A \quad \neg A}{\bot}$

(9) $\dfrac{A(a)}{\forall x A(x)}$ (10) $\dfrac{\forall x A(x)}{A(a)}$

(11) $\dfrac{A(a)}{\exists x A(x)}$ (12) $\dfrac{\exists x A(x) \quad \begin{matrix}[A(a)] \\ C\end{matrix}}{C}$

Rule (3a), for example, adds a new root to the tree, transforming a derivation of *A* from unspecified assumptions into a derivation of $A \vee B$ from those same assumptions. Introductions are written on the left, eliminations on the right. ‘ $\bot$’ is a constant for falsity. A formula enclosed in square brackets indicates that assumptions of this form in the derivation of the premise displayed below it may be discharged by the inference in question.

In rules (9) and (12), *a* cannot occur in $A(x)$ and is called the ‘proper parameter’ of the inference; it must satisfy the following restrictions. In (9), *a* cannot occur in any assumption on which the premise depends; in (12), *a* cannot appear in *C* nor in any assumption upon which the premise *C* depends except for those of the form $A(a)$. Because they allow the discharge of assumptions, it is better to view applications of the rules $\rightarrow$-introduction and $\vee$- and $\exists$-elimination as operating on whole derivations rather than simply on their conclusions. A similar remark can be made about $\forall$-introduction because it requires that the derivation of $A(a)$ in its premise satisfy an extra condition. This system of introductions and eliminations constitutes minimal logic. A system equivalent to Heyting’s axiomatization of intuitionistic logic is obtained by adding a rule which allows any formula to be inferred from a falsehood.

$\dfrac{\bot}{A}$

Classical logic can be obtained by adding to the intuitionistic system as axioms all instances $A \vee \neg A$ of the law of the excluded middle, or a rule such as the following.

$\dfrac{\neg\neg A}{A}$

The major premise of an elimination is the formula whose principal operator is displayed in the statement of the rule. A ‘maximum formula occurrence’ in a derivation is both the conclusion of an introduction and the major premise of an elimination. It constitutes a needless detour and can be removed. This can be illustrated in the case of implication by the following pair of derivations (where Π_1 and Π_2 are derivations of *A* and *B*, respectively):

$$\dfrac{\dfrac{\Pi_1}{A} \quad \dfrac{\begin{matrix}[A] \\ \Pi_2 \\ B\end{matrix}}{A \rightarrow B}}{B}$$

The one on the right is obtained from Π_2 by replacing each occurrence of the assumption *A* discharged by the

application of $\rightarrow$-introduction by a copy of the derivation Π_1 of *A*. If no assumption is discharged, the derivation on the left is just replaced by Π_2. In either case, the result is a more direct derivation of the same conclusion from the same or fewer assumptions. A transformation of this kind is called a 'reduction' step, and similar reductions can be defined for the other operators. The special form of the elimination rules for '$\vee$' and '$\exists$' give rise to what are called 'maximum segments'. These consist of consecutive occurrences of the same formula such that the first is the conclusion of an introduction, the last is the major premise of an elimination and all except the first are conclusions of an application of $\vee$- or $\exists$-elimination. To remove such segments it is necessary to permute applications of $\vee$- and $\exists$-elimination with other inferences.

A derivation is said to be 'normal' if it contains no maximum formula occurrence or segment. Gentzen's normal form theorem states that for every derivation in the intuitionistic system, there is a normal one of the same conclusion from the same or fewer assumptions. It is proved by prescribing a method for systematically removing all detours from a derivation, and thus a stronger result is established - sometimes called the 'normalization theorem' - namely, that every derivation Π can be *reduced* to one in normal form. The reduction steps can be so chosen that every sufficiently long sequence of them beginning with Π terminates in a unique normal derivation. This is called the strong normalization theorem. Roughly speaking, a normal derivation is constructed by first breaking up its assumptions using eliminations and then building up its conclusion using introductions. That is why every formula appearing in the derivation will be a subformula of an assumption or the conclusion. All three forms of the theorem have been exploited to yield various proof-theoretic results for formalized mathematical theories. In addition, the significance of the normalization procedure itself has been studied in a more general context. It has been argued that the steps required to reduce a derivation to normal form do not change its meaning. In consequence, derivations which reduce to the same normal form have the same meaning or express the same proof. More controversially, the converse has also been claimed to hold.

2 The sequent calculus

The theorems discussed at the end of the previous section do not extend straightforwardly from the intuitionistic to the classical version of natural deduction. By exploiting the definability of disjunction and existential quantification in classical logic, however, they can be shown to hold for a system of natural deduction adequate for classical logic. A rather more sophisticated argument is required to establish them for a classical natural deduction calculus in which all the usual logical constants are taken as primitive. Gentzen, however, did not extend his theorem to the classical system described above. He chose rather to reformulate it as a calculus of sequents. It is a trivial matter to rewrite the introductions and eliminations as sequent rules by placing the assumptions on which a formula depends on the left-hand side of the sequent. The rules for '$\rightarrow$', for example, will look as follows.

$$\frac{A,\Gamma\vdash B}{\Gamma\vdash A\rightarrow B} \qquad\qquad \frac{\Gamma\vdash A\rightarrow B \quad \Delta\vdash A}{\Gamma,\Delta\vdash B}$$

Although assumptions have been eliminated in favour of axioms of the form $A \vdash A$, nothing else of significance has been changed. In fact, the resulting calculus is just a notational variant of natural deduction. Gentzen's idea was to rewrite only the introduction rules in this way, and to replace the eliminations by new rules for introducing a formula on the left side of a sequent. These left rules are displayed below. (*a* cannot occur anywhere in the conclusion of the last rule.)

$$\frac{A, \Gamma \vdash C}{A \wedge B, \Gamma \vdash C} \qquad \frac{B, \Gamma \vdash C}{A \wedge B, \Gamma \vdash C}$$

$$\frac{A, \Gamma \vdash C \quad B, \Gamma \vdash C}{A \vee B, \Gamma \vdash C}$$

$$\frac{\Gamma \vdash A \quad B, \Delta \vdash C}{A \rightarrow B, \Gamma, \Delta \vdash C}$$

$$\frac{\Gamma \vdash A}{\neg A, \Gamma \vdash}$$

$$\frac{A(a), \Gamma \vdash C}{\forall x A(x), \Gamma \vdash C}$$

$$\frac{A(a), \Gamma \vdash C}{\exists x A(x), \Gamma \vdash C}$$

The rules may be read in different ways. Their connection with natural deduction is best brought out by interpreting the symbol ‘ $\vdash$’ as derivability. Then the last of them, for example, asserts that a derivation of *C* from $A(a), \Gamma$ can be transformed into one of *C* from $\exists x A(x), \Gamma$ (subject to the restriction on *a*).

In addition, Gentzen introduced some structural rules: ‘interchange’ for permuting formulas on a list, ‘contraction’ for amalgamating two occurrences of the same formula, and ‘thinning’ or ‘weakening’ for adding formulas to a list. Because an empty list on the right of a sequent can be interpreted as falsity, there is no longer any need for the constant ‘ $\bot$’. Furthermore, the intuitionistic negation rule can now be derived because thinning on the right justifies the inference from $\Gamma \vdash$ to $\Gamma \vdash A$. In the presence of the structural rules, it does not matter whether the left rule for ‘ $\vee$’ is formulated as above or as follows.

$$\frac{A, \Gamma \vdash C \qquad B, \Delta \vdash C}{A \vee B, \Gamma, \Delta \vdash C}$$

And likewise for the other two premise rules, both left and right. Recently J.-Y. Girard, in his work on linear logic (see Girard 1995), has embarked upon a searching investigation of the proof-theoretic significance of the structural rules, and of the consequences of omitting or weakening them in various ways. In their absence, he distinguishes two versions of disjunction, for example: an additive and a multiplicative one according to which formulation of its left rule is adopted.

3 Comparing sequents and natural deduction

It is easy to translate a derivation of the sequent $\Gamma \vdash A$ into a derivation in natural deduction of *A* from assumptions included in the list Γ - into a normal one, in fact. Call this derivation its $\mathcal{N}$ translation. Applications of right rules translate directly into introductions. The situation with left rules is only slightly more complicated. Consider conjunction, for example, and suppose that Π is the $\mathcal{N}$ translation of a derivation of $A, \Gamma \vdash C$, then the required derivation of *C* from assumptions in $A \wedge B, \Gamma$ is obtained by substituting copies of the two-line derivation

$$\frac{A \wedge B}{A (\dagger)}$$

for the appropriate occurrences of the assumption *A* in Π.

Converting natural deduction derivations into sequent ones is less straightforward. Introductions correspond as before to applications of a right rule. To translate eliminations, however, we need not only the corresponding left rule, but also a rule called ‘cut’.

$$\frac{\Gamma \vdash A \qquad A, \Delta \vdash C}{\Gamma, \Delta \vdash C}$$

With the addition of this rule every sequent derivation will still have an $\mathcal{N}$ translation, although we can no longer be sure that it will be normal. The $\mathcal{N}$ translation of a derivation which ends with the cut displayed above is obtained by substituting copies of the $\mathcal{N}$ translation of the derivation of its left premise for the appropriate occurrences of the assumption *A* in the $\mathcal{N}$ translation of the derivation of its right one.

To see why cut is needed for translating the elimination rules, consider again the case of conjunction and suppose that we have already succeeded in translating a derivation Π of $A \wedge B$ from assumptions Γ into a derivation δ of the sequent $\Gamma \vdash A \wedge B$. Then what needs to be shown is that δ can be converted into a derivation of $\Gamma \vdash A$. This is accomplished by a cut applied to the conclusions of δ and a derivation whose $\mathcal{N}$ translation is $(\dagger)$ above, as shown in the following figure.

$$\dfrac{\begin{matrix}\delta\\ \Gamma \vdash A \wedge B\end{matrix} \qquad \dfrac{A \vdash A}{A \wedge B \vdash A}}{\Gamma \vdash A}$$

This translation exploits the fact that the result of applying $\wedge$-elimination to Π is the same as substituting Π for the assumption $A \wedge B$ in the derivation $(\dagger)$ above. The other elimination rules are handled similarly.

Clearly, every formula appearing in the premise(s) of a left or right rule is a subformula of a formula appearing in its conclusion, and the same holds for the structural rules. Consequently, any derivation constructed only by the use of these rules will be such that it contains only subformulas of formulas occurring in its final sequent. Gentzen's normal form theorem in this context takes the form of a cut-elimination theorem, and he was able to prove that every derivation can be transformed into a cut-free derivation of the same sequent. His proof, although similar in kind to the one for natural deduction, does involve additional complications. Furthermore, cut-free forms are not in general unique. It would appear therefore that little advantage has been gained by passing from natural deduction to a sequent calculus, especially since sequent derivations are for the most part less intuitive.

In favour of sequent derivations is the fact that the absence of assumptions makes them easier to work with from a metamathematical standpoint. To verify the correctness of a sequent derivation it is enough to check it locally, that is, to look at each sequent and its immediate successors individually. There are no global conditions on the derivation that need to be satisfied (as, for example, that a certain parameter cannot appear in any assumption). This also makes coding derivations by means of Gödel numbers much easier. A more significant advantage, however, concerns the relationship between the calculus described above and classical logic. Gentzen observed that, by the simple expedient of allowing a list containing more than one formula to appear on the right-hand side of a sequent, he could obtain a system adequate for classical logic. The classical versions of the right and left rules for ' $\rightarrow$', for example, read as follows.

$$\frac{A, \Gamma \vdash \Delta, B}{\Gamma \vdash \Delta, A \rightarrow B} \qquad\qquad \frac{\Gamma \vdash \Delta, A \qquad B, \Psi \vdash \Phi}{A \rightarrow B, \Gamma, \Psi \vdash \Delta, \Phi}$$

All the remaining rules, including cut, are similarly generalized; no new rules need to be added. To see that the resulting calculus is adequate for classical logic, note that the sequent $\vdash A \vee \neg A$ is now easily derivable. Applying $\neg$-right to $A \vdash A$ yields $\vdash A, \neg A$, from which the desired sequent follows by two applications of $\vee$-right and a couple of structural inferences. It is possible therefore to give a single proof of the cut-elimination theorem for both classical and intuitionistic systems. The proof for the classical system involves no new ideas, and it specializes immediately to a proof for the intuitionistic one. One need simply observe that each reduction prescribed in the proof yields an intuitionistic derivation when applied to one.

Gentzen's theorem has been fruitfully applied to yield a variety of results in proof theory. The Craig interpolation theorem, for example, follows from it easily, as do various decidability results. Gentzen himself utilized the method of cut elimination to prove the consistency of formal number theory, that is, of a system obtained by augmenting the sequent calculus with appropriate arithmetical principles. (In fact, his original proof was for a theory based on natural deduction, but he subsequently rewrote it for the sequent calculus.) His methods have since been adapted and extended, in many different ways and to a variety of different situations. A version of the cut-elimination theorem for second-order logic, for example, has yielded a consistency proof for analysis, formalized as a theory of second-order arithmetic (see Proof theory §4). The information provided by results such as these depends upon the methods required to establish them, and their significance is understood differently in different foundational traditions. Nevertheless, there is no doubt that the methods pioneered by Gentzen have been one of the mainstays of proof theory in the tradition of Hilbert, as it has developed in the wake of Gödel's theorems.

Although cut-free derivations are in some sense simpler and more direct than their counterparts containing cuts, the elimination procedure described by Gentzen increases the length of a derivation each time a cut is removed

from it. Furthermore, this turns out to be an essential feature of any cut-elimination procedure. The same holds true for the elimination of maximum formula occurrences from natural deduction derivations and, as one might expect, the efficiency of the tableau method described below is correspondingly increased when an analogue to the cut rule is added to the system. This simple fact has given rise to a great deal of research on the complexity of derivations, and very refined bounds on the length of cut-free ones have been established for a variety of systems and theories. The subject of complexity has attracted particular attention from researchers interested in implementing automated reasoning systems (see Complexity, computational).

4 Tableau systems

The discussion of the previous sections was based on an interpretation of the sequent calculus as characterizing the relation of derivability under assumptions in natural deduction. With the passage from intuitionistic to classical sequents, this interpretation is no longer possible. The classical rules are easily seen to be correct under a semantic interpretation, however, according to which $\Gamma \vdash \Delta$ is taken to mean that for every model of Γ there is at least one formula in Δ that is true in it. If the rules are read backwards, from conclusion to premise(s), they represent steps in the search for a counterexample to $\Gamma \vdash \Delta$, a model in which all the formulas in Γ are true, while all those in Δ are false. To find a counterexample to $\Gamma \vdash \Delta, A \wedge B$, for example, we may search in one of two directions, either for a counterexample to $\Gamma \vdash \Delta, A$ or for one to $\Gamma \vdash \Delta, B$. The first person to exploit this feature of the rules seems to have been E.W. Beth. It underlies the tableau system for classical logic which he formulated in the mid-fifties (see his later work of 1964 for details). However, the general idea of a no-counterexample treatment of logic is also to be found in the works of other logicians of the period, including J. Hintikka, S. Kanger and K. Schütte.

A semantic tableau for the sequent $\Gamma \vdash \Delta$ begins as a figure consisting of two columns, with the formulas in Γ listed at the head of the left one and the formulas in Δ at the head of the right. The rules extend the tableau by operating on individual formulas in these lists. A left rule operates on *A* in Γ and allows us to enter into the tableau subformulas of *A* in such a way that the truth of the left entries together with the falsity of the right ones together constitute a sufficient condition for *A* to be true. Similarly, a right rule operates on *A* in Δ and allows us to enter subformulas whose truth and falsity are sufficient for *A* to be false. As before, there are pairs of rules for each of the logical constants, and some of these rules require the tableau to split into a pair of subtableaus, each with its own left and right column. Since all the classical connectives and quantifiers are definable in terms of ‘ $\neg$’, ‘ $\rightarrow$’ and ‘ $\exists$’, it will be sufficient to list tableau rules for just these three operators:

If $\neg A$ appears in the left column, write A in the right one.
If $\neg A$ appears in the right column, write A in the left one.
If $A \rightarrow B$ appears in the left column, split the tableau into two subtableaus, write B in the left column of one subtableau and A in the right column of the other.
If $A \rightarrow B$ appears in the right column, write B below it and A in the left column.
If $\exists x A(x)$ appears in the left column, write $A(a)$ in the left column, where a is a new parameter.
If $\exists x A(x)$ appears in the right column, write $A(a)$ in the right column, where a is any parameter that has already been introduced into the tableau (or a new one if none has been introduced).

The left rule for ‘ $\rightarrow$’, for example, reflects the fact that in classical logic there are two ways to verify an implication: its antecedent may be false or its consequent true. The right rule reflects the fact that there is only one way to refute one: its antecedent must be true and its consequent false. In all cases except the last, the formula to which the rule has been applied is cancelled to indicate that the rule cannot be applied to it again. In the case of right ‘ $\exists$’, the possibility of applying the rule with respect to a different parameter is left open. A subtableau is closed if there is at least one formula which occurs in both its left and right column. A tableau is closed if all its subtableaus are closed. $\Gamma \vdash \Delta$ is derivable if it has a closed tableau. Finally, a tableau has been terminated if it is not closed, but no further rules are applicable to any of its subtableaus.

By way of example, the following closed tableau establishes the validity of the sequent

$\neg \exists x \neg (A(x) \rightarrow B) \vdash \exists x A(x) \rightarrow B.$

$\neg\exists x\neg(A(x) \rightarrow B)$		$\exists x A(x) \rightarrow B$	
$\exists x A(x)$		B	
$A(a)$			
		$\exists x\neg(A(x) \rightarrow B)$	
		$\neg(A(a) \rightarrow B)$	
$A(a) \rightarrow B$			
1	2 B	1 $A(a)$	2

Each line is obtained from a previous one by applying one of the rules for tableau construction. Notice that the initial tableau splits into two subtableaus after line six. (The first and third cells of line seven are the left and right columns of one, the second and fourth of the other.) Both subtableaus are closed, the one because $A(a)$ appears on the left in line three and on the right in line seven, and the other because *B* appears on the right in line two and on the left in line seven.

The rules for tableau construction are really nothing other than upside-down versions of the classical sequent rules. Indeed, one need do little more than invert a closed tableau to convert it into a cut-free derivation in the sequent calculus. There is no need to augment the tableau rules by a rule analogous to cut because their deductive adequacy can be demonstrated directly without reference to the derivations of any other system. The rules may be applied to a sequent in any order (although it is convenient to postpone applying right '$\exists$' for as long as possible) and three possibilities can arise:

(1) The tableau closes after a finite number of steps, in which case the disjunction of the formulas in Δ is a classical consequence of the formulas in Γ.
(2) The tableau is terminated after a finite number of steps. This will be because every uncancelled formula (other than existential ones to which right '$\exists$' is no longer applicable) is atomic. It is then easy to construct a model in which each atomic formula appearing on the left of an open subtableau is true and each one appearing on the right is false. Such a model turns out to be a counterexample to the original sequent in the sense that all the formulas in Γ are true in it while those in Δ are false.
(3) The tableau is never terminated. This possibility arises because right '$\exists$' may be applied repeatedly to a formula as needed. Nevertheless, as Beth showed, we can prove generally that a counterexample can also be constructed from any such infinite tableau.

The upshot is that the rules of tableau construction provide a complete proof procedure for classical logic. Despite their semantic motivation, it should be emphasized that these are purely syntactic rules - and hence that there is a cut-free derivation of every derivable sequent in the sequent calculus as well. This semantic approach to the cut-elimination theorem is less elementary than Gentzen's original proof. More significantly, however, the connection between a derivation and its cut-free form is lost.

Because tableaus may split into subtableaus, the method is cumbersome to use. A considerable simplification was effected by Raymond Smullyan, who introduced the idea of 'signed' formulas. Given $\Gamma \vdash \Delta$, the formulas in Γ receive the sign T and those in Δ the sign F. A tableau now begins with a single list of signed formulas, and left and right rules are reformulated as rules for formulas with the signs T and F respectively. The result is a single tree, rather than a series of tableaus, which branches instead of splitting. A closed branch will contain an occurrence of some formula *A* with the sign T and another occurrence with the sign F, and a tree is closed when every branch is closed. (Alternatively, one can dispense with signs and form a single list from the formulas in Γ together with the negations of those in Δ.) It is in this form, rather than the original one, that the tableau method has found its way into the literature. An analogous modification of the sequent calculus was introduced by Kurt Schütte. Here the effect is to make derivations less intuitive, although the calculus is more concise and better suited for some applications.

Just as natural deduction seems to be a more appropriate system for intuitionistic logic, so tableaus seem better adapted to express classical consequence. Nevertheless, as Beth showed, they can be modified to yield a proof procedure for intuitionistic logic. Subsequently, tableau techniques were extended to modal systems, by Kripke among others, and what are now called Kripke models have their origin in constructions deriving from these.

Natural kinds

Objects belonging to a natural kind form a group of objects which have some theoretically important property in common. For example, rabbits form a natural kind, all samples of gold form another, and so on. Natural kinds are contrasted with arbitrary groups of objects such as the contents of dustbins, or collections of jewels. The latter have no theoretically important property in common: they have no unifying feature. Natural kinds provide a system for classifying objects. Scientists can then use this system to predict and explain the behaviour of those objects. For these reasons, the topic of natural kinds is of special interest to metaphysics and to the philosophy of science.

1 The notion of natural kinds

Objects belonging to a natural kind form a group of objects which have some theoretically important property, or properties, in common. Standard examples of natural kinds include biological species such as rabbits, oaks and whales, chemical elements and compounds such as oxygen, carbon and aluminium, and stuffs such as salt, wool and heat. An object's membership of a given natural kind bears upon how that object will behave, the properties it can or cannot acquire, and the types of interaction in which it can figure. Natural kinds thereby provide a scheme of classification for science to chart (see Taxonomy). Scientists can use such a system to predict, explain and (perhaps) control the behaviour of those objects. Knowledge of natural kinds can also provide a basis for inductive and counterfactual scientific reasoning: knowledge about how past members of a natural kind behaved may warrant beliefs about how present or future members of that kind will behave, as well as how hypothetical members of that kind would behave.

Closely related is the question regarding which predicates are 'projectible': the question of which predicates are admissible in inductive reasoning. Predicates such as 'is a rabbit' and 'is an oak' are admissible, but not every predicate is. The predicate 'is a roak', which is hereby defined as being true of an object if and only if it is a rabbit or an oak, seems inadmissible. The notion of a natural kind may help in explicating this distinction between projectible and non-projectible predicates (see Goodman, N. §3).

Again, a theory's terms are apparently open to deviant interpretations. A theory containing (say) the predicate 'is a rabbit' is standardly interpreted as meaning rabbit, but this predicate can be deviantly interpreted as meaning (say) rabbit or oak. To meet this problem, we might invoke the principle that among meaning-assignments we should prefer those in which the assigned meaning concerns natural kinds, rather than non-natural ones.

2 Two major questions

The topic of natural kinds raises two major related questions. There is a metaphysical question: what is a natural kind? Natural kinds are standardly distinguished from arbitrary groups of objects, such as what you had for breakfast. They are also standardly distinguished from so-called artefact kinds such as books, tables or cars. A full account of the metaphysics of natural kinds should clarify these distinctions and explain the rationale behind them. Furthermore, it should explain the sense in which different members of a natural kind have a property in common. On one possible account, different members of a natural kind share a universal: they have a property which is literally identical between them (see Universals). But on a rival account, different members of a kind have a property in common only in the sense that each member bears a certain similarity relation to every other member of the kind.

There is also an epistemological question: how do we tell what natural kinds there are? Every object has many properties, yet we think that only some properties determine natural kinds. But what reasons guide our thinking that certain properties rather than others determine natural kinds? Furthermore, our beliefs about what natural kinds there are, and which objects belong to them, may be inaccurate to some degree. These beliefs may only approximately describe what natural kinds there are, and what their members are. But then how are we to establish how accurate these beliefs are?

Such metaphysical and epistemological questions are also of interest outside philosophy. For instance, it is a live issue among biologists whether species are natural kinds, and there is a further issue of whether it is morphological, reproductive or phylogenetic factors which determine a creature's membership of a given species

(see Species).

3 Essentialism

Locke (1689) and, following him, Kripke (1972) and Putnam (1975), each offer an account of how our understanding of a given natural kind can develop over time. At an initial stage, speakers classify certain objects as members of the same natural kind because they perceive those objects to have certain properties in common. Such common properties form the ‘nominal essence’ (Locke) or ‘stereotype’ (Putnam) associated with that kind. The speakers, however, further believe that these objects are members of the same natural kind if and only if they have some underlying, though perhaps currently unknown, common property. This is the ‘real essence’ of that kind. In the case of chemical elements, it will perhaps be some microstructural property. In the case of organisms, it will perhaps be some genetic structure. Moreover, given how laws of nature relate a kind’s real essence to its nominal essence, an object’s real essence explains why that object has the nominal essence that it does. It then falls to empirical science to discover the real essences of objects.

In sum, an object’s nominal essence serves as a heuristic, a guide for thinking whether that object is a member of a certain natural kind. But whether in fact that object is a member of the kind in question is determined by whether it has the appropriate real essence. For instance, various objects may once have been classified as members of the natural kind lemon because of their yellow appearance, tart taste, thick skin and oval shape. These properties form the kind’s nominal essence. However, scientific inquiry may subsequently reveal the real essence of lemons - a common genetic structure, let us suppose. Since something is a lemon if and only if it has this genetic structure, we may revise to some degree our original classification of which objects are lemons. On this view, fruit which are superficially similar to lemons but which have a different genetic structure, are not lemons. In contrast, unripe, mouldy, or squashed fruit with the same genetic structure as lemons are lemons, even though superficially they do not appear to be so.

Kripke and Putnam further argue that it is (metaphysically) necessary that something is a member of a given kind if and only if it has a certain real essence. Hence if the real essence of, for example, gold is a certain atomic number, then, necessarily, something is gold if and only if it has that atomic number. Kripke and Putnam conclude that there are certain *de re* necessities which can be discovered only empirically (see De re/de dicto; Essentialism). Other philosophers have since argued that essentialism about natural kinds entails that the laws of nature which govern kinds are also *de re* necessary.

4 Conventionalism

Kripke and Putnam assume that what natural kinds there are, and which objects are members of those kinds, are matters which obtain independently of our attempts at classification. Conventionalism about natural kinds denies this assumption. It says that our classification of objects into natural kinds does not reflect any pre-existing divisions in nature. Instead, it is based on human convenience, and its goal is the prediction and control of observable events, not the discovery of underlying essences.

Locke ultimately took this view. Frequently, he is interpreted as taking it for an epistemological reason, namely that real essences, if there are any, would be unobservable and so unknowable. More recently, Bas van Fraassen (1980) has taken a similar view, but for a different reason, believing that science need be concerned only with observable entities, and so not with real essences. Hence the latter are redundant: they are ‘metaphysical baggage’. The dispute between realists and conventionalists about natural kinds is then located within the more general dispute between scientific realism (which claims that science describes an unobservable world) and constructive empiricism (which is agnostic about whether science does this). A further reason for scepticism about essentialism about natural kinds, and one which Locke and van Fraassen share, is a suspicion of what *de re* or metaphysical necessity is supposed to be. The suspicion is that the thesis that there are necessities in nature is obscure, and that instead the only source of necessity lies in human conventions. Accordingly, the thesis that objects have real essences in virtue of which they are members of certain natural kinds is held to be infected with this obscurity.

Natural law

When made within the discourse of ethics, political theory, or legal theory or philosophy of law, the claim that there is a natural law is an offer to explain and defend certain claims often made, in different terms, in the discourse of moral argument, politics or law. In pre-theoretical moral discourse, certain choices, actions or dispositions may be asserted to be 'inhuman', 'unnaturally cruel', 'perverse' or 'morally unreasonable'. In pre-theoretical political discourse, certain proposals, policies or conduct may be described as violations of 'human rights'. In international law and jurisprudence, certain actions may be described as 'crimes against humanity' and citizens may claim immunity from legal liability or obligations by appealing to a 'higher law'. A natural law theory offers to explain why claims of this sort can be rationally warranted and true. It offers to do so by locating such claims in the context of a general theory of good and evil in human life so far as human life is shaped by deliberation and choice. Such a general theory can also be called a general theory of right and wrong in human choices and actions. It will contain both (1) normative propositions identifying types of choice, action or disposition as right or wrong, permissible, obligatory and so on, and (2) non-normative propositions about the objectivity and epistemological warrant of the normative propositions.

1 Why called natural? Why called law?

Theorists who describe their theory of good and evil, right and wrong, as a 'natural law theory' are not committed to asserting that the normative propositions which they defend are 'derived from nature' or 'read off' or 'inspected in the nature of things'. Still less are natural law theorists committed to claiming that the normative propositions they defend stand in some definite relationship to, or are warranted by, the 'laws of nature' in the sense of the regularities observed, and explanatory factors adduced, by the 'natural sciences'. Nor is the typical natural law theory (classical, medieval or contemporary) concerned with any alleged 'state of nature', in the sense of some golden age or state of affairs prior to human wrongdoing or to the formation of human societies or of states or political communities (see Laws, natural).

As for the term 'law', as understood in the phrase 'natural law', it does not connote that the relevant principles and norms have their directive force precisely as the imperatives or dictates of a superior will. Even when a natural law theorist argues (as most do) that the ultimate explanation of those principles and norms (as of all other realities) is a transcendent, creative, divine source of existence, meaning and value, the theorist usually will maintain also that moral precepts divinely commanded are commanded because fitting and obligatory, not fitting or obligatory because commanded (or that the source of their obligation is rather divine wisdom than divine will). Rather, the term 'law' in the phrase 'natural law' refers to standards of right choosing, standards which are normative, that is rationally directive and 'obligatory', because they are true and choice otherwise than in accordance with them is unreasonable.

The term 'natural' in this context signifies any one or more of the following: that the relevant standards are not 'positive', that is, are directive prior to any positing by individual decision or group choice or convention; that the relevant standards are 'higher' than positive laws, conventions and practices, that is, provide the premises for critical evaluation and endorsement or justified rejection of or disobedience to such laws, conventions or practices; that the relevant standards conform to the most demanding requirements of critical reason and are objective, in the sense that a person who fails to accept them as standards for judgment is in error; that adherence to the relevant standards tends systematically to promote human flourishing, the fulfilment of human individuals and communities.

2 Critique of scepticism and dogmatism

Historically, natural law theories have been articulated as part or product of a philosophical critique of ethical scepticisms (see Scepticism), and have included in their critique a differentiation of the rationally grounded norms of natural law from moral dogmatism or conventionalism. In contemporary thought, scepticism about natural law (and about all moral theories claiming to be objective or true) is very often based upon a logically illicit and rationally unwarranted inference from certain propositions about what 'is' the case to certain propositions about what is good or obligatory. This particular form of invalid reasoning was assiduously employed in the ancient manuals of scepticism (notably by Sextus Empiricus, *c*. AD 200), and reintroduced into European discourse in the

sixteenth century. Sextus Empiricus uses the term ‘dogmatism’ to insinuate that all non-sceptical ethical theories, such as natural law theory, are uncritical; but this charge is not well grounded, and the term is used here to refer to moral positions held without openness to critical questions.

Examples of the invalid reasoning commonly encountered include:

X is not universally regarded as good/obligatory; therefore X is not good/obligatory.
In modern thought X is widely regarded as not good/obligatory; therefore X is not good/obligatory.
In contemporary society X is widely regarded as good/obligatory; therefore X is good/obligatory.
I have a sentiment of approval of X; therefore X is good (or worthwhile…or obligatory…), at least for me.
I have opted for or decided upon or am committed to the practical principle that X ought to be done; therefore X ought to be done, at least by me.

As this list of *non sequitur*s suggests, there is a link between ethical scepticism (at least in its popular forms) and ethical conventionalism. There are many natural law theories, on the other hand, which are not guilty of these or other fallacies, fallacies that consist in concluding to a normative judgment from premises which include no normative proposition.

David Hume (1740) suggests that ‘every system of morality’ prior to his critique illogically purports to infer ought or ought not from is or is not (see Hume, D.). The suggestion is ungrounded, though the illicit inference may perhaps be detected in certain eighteenth-century rationalists (especially Samuel Clarke) whom Hume seems to have had prominently in mind when writing this part of his *Treatise*. In so far as Hume’s predominant view concerning the nature and basis of moral judgments was that they are judgments about what characteristics and actions arouse approval or disapproval, Hume was himself plainly guilty of this kind of illegitimate inference. The same cannot be said of Plato, Aristotle and Aquinas, for example.

Max Weber is often, and with some plausibility, said to have introduced the modern form of the ‘fact/value distinction’ and denial of the ‘objectivity of value judgments’. Weber’s primary argument for this denial seems to have been simply that people, or educated people, in fact disagree with each other about values. This argument has no more validity than the popular arguments listed above; the fact of disagreement no more disproves a proposition than the fact of agreement proves it. Weber had three other lines of argument. The first was a Neo-Kantian argument that all judgments must rest upon presuppositions, and that selection among competing presuppositions must be non-rational. This argument is self-refuting in its general form, and there is no way to limit it (as Weber sought to do) to judgments of value. Weber’s next argument pointed, like Sartre after him, to certain supposed political and/or ethical dilemmas before which reason is supposed to fall silent. In fact, however, such ‘dilemmas’ are no more than a stimulus to a more nuanced and resourceful practical reasoning, which may identify more than one option as morally acceptable in the situation. Weber’s final argument alleged that there are distinct and incommensurable ‘spheres’ of practical judgment, such as the political, the erotic and the ethical, each with its own ultimate values between which reason cannot adjudicate because reason operates only within spheres. This final claim is never defended by Weber, and is contradicted by his own acknowledgement that the spheres interpenetrate one another.

Perhaps the most fruitful critique of ethical scepticism is one which takes its cue from Aristotle’s critique of general scepticism (*Metaphysics* IV). If sceptics are willing to affirm their position as rationally warranted they can be shown to be denying (1) something given, instantiated, in the activity of rationally considering and proposing their or any other position, and/or (2) some proposition to which their assertion of their position rationally commits them. In the case in hand, the relevant givens include the rationality norms which guide the rational inquiries of those who choose to follow them and to resist temptations to reach conclusions by sub-rational processes; and the propositions to which an argued assertion commits the person asserting it include the proposition that knowledge of truth (at least the truth of such propositions as the one asserted) is a good worth pursuing and instantiating in that argument and assertion, a good worthwhile for its own sake as well as for any instrumental advantage it might yield.

3 Cognitivism and natural law theories

Not every non-sceptical ethics is appropriately called a natural law theory. Natural law theories are distinguished

from the broader set of cognitivist or objectivist ethical theories in four main ways.

First, they are differentiated from any ethics in a Kantian mould by their willingness to identify certain basic human goods, such as knowledge, life and health, and friendship, as the core of substantive first principles of practical reasoning (see Kantian ethics). Taken together, these basic human goods give shape and content to a conception of human flourishing and thus, too, to a conception of human nature. For an axiom of Aristotle's method, deployed more generally by Aquinas, shows that while nature is metaphysically (ontologically) fundamental, knowledge of a thing's nature is epistemically derivative: an animate thing's nature is understood by understanding its capacities, its capacities by understanding its activities, and its activities by understanding the objects of those activities. In the case of the human being the 'objects' which must be understood before one can understand and know human nature are the basic goods which are the objects of one's will, that is, one's basic reasons for acting, that give reason for everything which one can intelligently take an interest in choosing.

Second, natural law theories are distinguished from any theory which asserts that moral truths are known essentially by discrete 'intuitions' (see Intuitionism in ethics §3). Rather, these theories argue that specific moral judgments concerning obligation or right are applications or specifications of higher principles. The first principles of the 'system' are known by insight without deduction via any middle term (they are *per se nota*: Aquinas, *Summa theologiae* IaIIae.94. 2). But the insights whose content is the self-evident principles of practical knowledge are not intuitions - insights without data. Rather they are insights whose data are, in the first place, natural and sensory appetites and emotional responses. These data are subsequently enriched by theoretical knowledge or true opinion about possibilities (for example, about what threatens and enhances health, or about what knowledge is available), and by experience of disharmony (frustrated intentions). It should be added that the classical natural law theorists would reject Jacques Maritain's theory that the knowledge of first practical principles is 'connatural' or 'by affinity or congeniality' or 'through inclination' rather than conceptual. There is compelling reason not to accept Maritain's claim that Aquinas must have been referring to such 'knowledge' when saying (in the passage cited above) that 'reason naturally understands as good all the objects of man's inclinations'. For Aquinas all knowledge is conceptual (*De veritate* 4.2.5), and the understanding of basic human goods is quite ordinary, unmysterious, *conceptual* understanding (Grisez 1965), albeit practical, that is, directive or prescriptive ('is-to-be-done-and-pursued'), rather than theoretical or descriptive ('is'). The first principles of natural law are not inclinations, but fundamental human goods understood as reasons for action.

Third, natural law theories are distinguished from any fundamentally aggregative conception of the right and the just. For viable natural law theories postulate no one end to which all human actions might be effective means, no one value in terms of which one might commensurate alternative options as simply better or worse, and no one principle which, without further specification in other principles and norms, should guide deliberation and choice. Rather they claim to identify a number of basic human goods, none of which is simply a means to or simply a part of any other such basic good. A number of principles are also identified to guide ('morally') the choices necessitated by the variety of basic goods and reasons for action and the multiple ways of instantiating these goods and acting on these reasons for action by intelligent and creative choice (as well as by misguided choices whose primary motivation is not reasons but emotion).

Fourth, natural law theories typically differ from other ethical theories by offering to clarify not only the normative disciplines and bodies of discourse, but also the methods of the descriptive and explanatory social theories (political theory or political science, economics, legal theory and so on). How best can human societies and their formative concepts be understood, without illusions, but in a general way (as in a project such as Aristotle's *Politics* or Max Weber's *Wirtschaft und Gesellschaft (Economy and Society)*)? Could such projects be 'value-free'? Or must even descriptive-explanatory theorists, in selecting concepts, rely upon some definite conceptions of what is important in human existence? Must they not use such conceptions as criteria for selecting topics for study, and concepts for describing those topics? Must they not also employ such criteria in judging some types and instantiations of human institutions or practices to be the 'central cases' of such institutions or practices, and also in judging some uses of terms such as 'law' or 'constitution' or 'authority' to be, for critical descriptive theory, the 'focal' uses and senses of those terms? And must not such conceptions and criteria of importance be the subject, not of selection by 'demonic' personal preference (Weber) or silent conformism to academic fashion or political *parti pris*, but rather of an open, public, critical justification? Natural law theories of the classical type, such as those of Aristotle and Aquinas, claim to offer such a justification (see Finnis 1980).

4 Derivation of positive law

The history of moral and political philosophy, and of natural law theory, is much affected by the lacunae in Aquinas' work. He was the thinker who most clearly articulated and developed the elements of practical philosophy in Aristotle (and thus, in a sense, in Plato), so as to represent them as propositions of or about natural law. Yet he failed to give a clear, full, careful and consistent statement of the first principles of practical reason, and a satisfying set of illustrations of the way in which first practical principles (such as 'human life is a good to be advanced and respected') or first moral principles (such as the 'golden rule') are given specificity in less fundamental principles and norms. This failure contributed significantly to the spread of voluntarist and fideistic currents which virtually overwhelmed the tradition of natural law theory as a living school of thought.

Aquinas was the first philosophical thinker to exploit the concept of 'positive law' which emerges in mid twelfth-century theological and juristic speculation. He gave an original and helpful sketch, scarcely surpassed even today, of the differing types of relationship between the high-level principles of natural law and (1) the more specified principles which can be attained by practical reasoning about the implications of those principles in recurrent types of human predicament and opportunity; and (2) norms, rules, precepts and juridical institutions which cannot be said to be required as the conclusion of any course of practical reasoning, yet which are in some other way rationally connected to, or derived from, principles of the first two sorts, and are authoritative for upright judges and good citizens if and when chosen and promulgated ('posited') by an appropriate authority. Laws, rights and institutions derived in the second way are 'positive', yet have much the same moral force in conscience as the higher-level principles of natural law, provided that their positing was by a person or body constitutionally authorized to make such decisions and making them without serious disregard either for other relevant moral principles and rights or for the 'common' (as opposed to partisan) good of all the members of the community subject to their authority.

This second mode of derivation was called by Aquinas *determinatio*, which might be translated 'concretization'. It is best understood by a comparison such as he offered by way of explanation. From his commission ('build a maternity hospital for our town') an architect can deduce various specifications (the building must be more than one metre in height, and must include doors, means of warming the spaces in winter, and so on). But no amount of attention to the commission (the 'principle' of his work) and to the circumstances (including the 'nature of things') will yield a single, rationally required answer to the unavoidable questions. Should the doors be 2.1 or 2.2 metres high? Of this metal or that? Questions of this kind must be answered by decisions (*determinationes*) which are rationally under-determined, yet intelligibly related to (and in this weak sense 'derived from') the master principle (the commission taken with its more or less necessary implications).

In this account the sheer positivity of much of a country's legal system is fully acknowledged. But at the same time the moral significance of the law's directives and institutions is affirmed and explained. The affirmation is conditional. If the relationship of 'derivation', albeit nondeductive and 'free', is broken by *ultra vires* (lack of authority) or unjust discrimination or violation of inviolable rights, the positive law's proper moral authority is eliminated. From the point of view of the conscientious judge, citizen or indeed legislator, this lack of the proper ('normal') moral authority was marked by the sayings found in Plato, Cicero, Aquinas and most of the philosophical, theological and juridical tradition down to the nineteenth century: an unjust law, albeit valid by the legal system's own criteria of validity (and in this sense properly described as a law), is not really a law, or is not a law *simpliciter*, that is, without qualification. It can have some collateral obligatoriness, in that it may be unfair to others to disobey it publicly (for example, because doing so would encourage others to disobey other laws without good reason). This classical thesis, *lex iniusta non est lex* (an unjust law is not a law), properly interpreted, is fully compatible with the jurist's or historian's wish to employ an amoral criterion of 'legal validity' or historical cognizability (see Aquinas, T. §13).

5 Inviolable human rights

The collapse of Christianity and other religious cultures, as the matrix for contemporary legal and political orders, has posed a challenge to those who wish to affirm that there is a natural law. In general, the challenge is to show that, even without the support of a religiously warranted ethic (revealed divine law) having an identical or overlapping content, there are philosophically sound reasons to affirm the truth of non-posited principles or norms

which, although not claiming to be authoritative because posited, are sufficiently definite to exclude gross ‘crimes against humanity’ (Nuremberg, 1945; chattel slavery; nonvoluntary euthanasia; and so forth) and to underpin the main institutions of civilized societies (family, property, religious liberty and so forth).

In particular, the challenge is to show that aggregative conceptions of moral and political reasoning, such as classical or contemporary utilitarianism or consequentialism or ‘economic analysis of law’, are unsound (see Utilitarianism §5; Consequentialism §2; Law, economic approach to §3).

Contemporary work in natural law theory therefore includes extensive attempts to criticize aggregative ethics, by showing that their conceptions of value overlook some or all of the basic human goods, and/or that their master principle of maximizing value overlooks the incommensurability not only of one basic human good relative to other such goods, but also of particular instantiations of even one and the same good in alternative options for morally significant choice. The supposition of those undertaking these critiques is that, if they are successful, the way will be open to identifying a richer set of moral principles guiding choice. A working postulate has been that any principle which has been the organizing or dominant principle of an entire philosophical ethic (for example, Kantian universalizability, Epictetan detachment, the principle of commitment expounded by Royce and Marcel) has some place in a developed natural law theory.

But theoretical reflection has yielded a more systematic and unifying ‘master principle of morality’. This principle is reached by way of the consideration that, so far as it is in one’s power, one should allow nothing but the principles corresponding to the basic human goods to shape one’s practical thinking. Aquinas’ first practical principle, ‘Good is to be done and pursued and evil avoided’, taken as it stands, requires only that one not act pointlessly, that is without reason; it requires only that one take at least one of the principles corresponding to a basic human good and follow through to the point at which one somehow instantiates that good through action. The first moral principle makes the stronger demand, not merely that one be reasonable enough to avoid pointlessness, but that one be entirely reasonable in one’s practical thinking, choice and action. It can be formulated: in voluntarily acting for human goods and avoiding what is opposed to them, one ought to choose and otherwise will those and only those possibilities whose willing is compatible with a will towards integral human fulfilment (that is, the fulfilment of all human persons and communities).

Integral human fulfilment, so defined, is not a goal towards which actions could be organized as means. But it is not empty of critical force, in identifying choices motivated by emotion fettering and deflecting reason. Unfairness, acting contrary to the golden rule (a principle superior in determinacy to Kant’s substitute, universalizability (see Kantian ethics §4)), is one sort of willing that is incompatible with openness to integral human fulfilment. A choice to destroy some instantiation of basic human good out of hatred is another. A choice precisely to destroy or damage some instantiation of a basic human good as a means to some other end is yet another, which comes into view as a demand of reason once the critique of aggregative theories has demonstrated the rational incommensurabilities overlooked by those who think that the goods promised by the end ‘outweigh’ the destruction or damage to human personal goods which is intended in a choice of this type.

This third moral principle corresponds not only to the traditional ‘the end does not justify these means’ but also to the Kantian ‘treat humanity always as an end and never as a means only’ - though ‘humanity’ is to be understood without Kant’s dualistic restriction of it to the rational faculties as such. It is a principle specified (made more specific) in the form of the traditional moral norms against murder and fraud. As such it is the backbone, so to speak, of traditional and modern legal systems. Articulated from the viewpoint of the beneficiaries of its moral protection, it is specified in those human rights which are not only fundamental but also, properly speaking, inalienable. It is the resultant of the classical principle that reason neither need nor should be the slave of the passions, together with both a precise understanding of free choice (enabling a firm and definite distinction between what is chosen and what is only accepted as a side-effect), and an understanding, developed in dialectic with Enlightenment and post-Enlightenment aggregative ethics, of the incommensurabilities of the goods, persons and probabilities at stake in alternative options for choice. In these and related ways one can think that natural law theory of the classic type is capable of philosophically warranted development (see Rights §3).

Natural philosophy, medieval

Medieval Latin natural philosophy falls into two main periods, before the rise of the universities (mainly in the twelfth century, when works were produced in connection with aristocratic patrons, monastic institutions or cathedral schools) and after their rise. In the earlier period, the dominant Greek influence is that part of Plato's Timaeus which had been translated into Latin and commented on by Calcidius. In the university period, the central works are those of Aristotle, often together with commentaries by Averroes.

Before the twelfth century, there was very little that could be described as natural philosophy. Such work as existed fell mainly into the genres of natural history (encyclopedic works using Pliny and the like as sources), didactic works (perhaps following a question and answer format on the model of Seneca's Natural Questions) or biblical commentary (especially commentaries on the Hexaemeron, or six days of creation). In the twelfth century, however, there are a number of original texts that may be considered as natural philosophy; examples include William of Conches' Philosophia mundi (Philosophy of the World), Bernard Sylvester's Cosmographia or Hildegard of Bingen's Scivias (Know the Ways). Greek natural philosophy also reached the Latin West through its influence on medical works and on art, for example on drawings of the cosmos, heaven, angels and hell.

The high and late Middle Ages (thirteenth and fourteenth centuries) was perhaps the preeminent period in all of history for natural philosophy. Natural philosophy was an official area of study in the arts faculties of medieval universities, alongside and distinct from the seven liberal arts (the trivium - grammar, rhetoric and logic - and the quadrivium - arithmetic, geometry, astronomy and music), moral philosophy or ethics, and first philosophy or metaphysics. As a subject of the arts faculty, natural philosophy was also defined as distinct from the subjects studied in the graduate faculties of theology, medicine and law.

The most common approach to natural philosophy in the thirteenth and fourteenth centuries was to comment on, or to dispute questions arising from, the natural works of Aristotle, especially his Physics, On the Heavens, On Generation and Corruption, Meteorology and On the Soul, as well as his various works in biological areas and the so-called Parva Naturalia, a group of short works on psychological topics. Medieval investigations of the cosmos that were largely mathematical - for example, most of astronomy - were considered in the Middle Ages to belong not to natural philosophy but to the quadrivium or perhaps to the so-called 'middle sciences' (such as optics, statics or the newly developed 'science of motion'). What little medieval experimental science there may have been (for instance that appearing in Peter Peregrinus' De magnete (On the Magnet), in Frederick II's De arte venandi cum avibus (On the Art of Hunting with Birds) and perhaps in some works on alchemy) seems not to have been done within the university setting. In the fourteenth century the new methods of medieval logic (supposition theory, propositional analysis or exposition, rules for solving sophismata and so on) are prominently used in natural philosophy.

Thirteenth- and fourteenth-century natural philosophy began with the general assumption of the Aristotelian world view, but later medieval natural philosophers did not hold to the Aristotelian view rigidly or dogmatically. In some cases, Christian faith seemed to contradict or to add to Aristotle's ideas, and natural philosophers tried to resolve these contradictions or to make the appropriate additions, as in the case of heaven and hell and angels. A number of difficulties, inconsistencies and sticking points in Aristotle were special subjects for discussion and received new resolutions as time went on.

Within the medieval university, natural philosophy was considered to be a part of general education, but it was also thought to be useful as a tool for theology and medicine. In northern universities such as Paris and Oxford, some of the most fundamental original work in natural philosophy was done in connection with the investigation of theological problems, for which natural philosophy, together with the other disciplines of the arts faculty, served as important aids. In Italian universities, where faculties of theology were less prominent or non-existent, natural philosophy was similarly tied to the resolution of medical questions.

European libraries contain many manuscript commentaries on Aristotelian works that still await modern analysis. The medieval university system did not as a rule identify, encourage or reward originality or uniqueness. Many natural philosophers claimed to be explaining Aristotle's meaning, even when they were introducing a novel interpretation of or variation on his ideas. When they made use of the ideas of earlier commentators, they rarely

mentioned them by name. What we now know about medieval natural philosophy is not a mirror reflection of what happened in the thirteenth and fourteenth centuries, because modern scholars have chosen to study those subjects and individuals relevant to their own present situations: Dominicans have emphasized the history of Dominican natural philosophy in such thinkers as Albert the Great and Thomas Aquinas, Franciscans have studied Franciscans such as John Duns Scotus and William of Ockham, historians of science have studied those individuals who had something to say about the subjects of modern science such as bodies, forces, velocities and resistances, logicians have studied logic, and so on. Because natural philosophy as such is not the focus of attention of many modern philosophers or other scholars, much medieval natural philosophy remains unread, sometimes in large-scale and handsomely produced commentaries on Aristotle's works, sometimes in hastily scribbled student notebooks.

1 Natural philosophy before and outside universities

From the beginning of the Middle Ages until the rise of the universities, relatively few people had time or opportunity for natural philosophy. At the beginning of the Middle Ages, Boethius set out to translate the works of Plato and Aristotle from Greek to Latin, and also proposed to write textbooks in Latin on the seven liberal arts. Before his imprisonment for treason in mid-career, he had succeeded in translating some of Aristotle's logical works and in editing textbooks of arithmetic, geometry and music. While in prison awaiting execution, he completed the classic *De consolatione philosophiae (The Consolation of Philosophy)*, in which he reflects on the pleasures of philosophy. Unfortunately, Boethius' early death prevented him from translating all of Aristotle's works or any of Plato's, and he did not translate any of Aristotle's natural philosophy.

Earlier, the Neoplatonist Calcidius had translated part of Plato's *Timaeus* into Latin. In this dialogue, Plato told a myth about the origins and nature of the cosmos and transmitted a number of Greek ideas (for example, that there are four elements, earth, water, air and fire, which can be transformed into each other). Because Aristotle's physical works were not available in Latin until the twelfth century, Calcidius' version of *Timaeus* was heavily used by early medieval thinkers as their source of knowledge about natural philosophy.

From 500-1000 AD, most of those who had the training and opportunity to study natural philosophy were connected with the church, as monks, priests, bishops or nuns. A century after Boethius, the bishop Isidore of Seville wrote his encyclopedic work *De rerum natura (On the Nature of Things)*, and a work of the same name was produced a further century later by the Venerable Bede in Northumbria. Both men were attempting to improve the low state of knowledge by condensing and transmitting the natural knowledge found, for example, in Pliny's *Natural History*, an encyclopedic compilation dating from the first century AD (see Encyclopedists). By the year 800, Charlemagne had established his court school under the direction of Alcuin of York, where the latter supervised the copying of manuscripts and oversaw the correction of existing copies of the Latin Bible. Among the Carolingians, Hrabanus Maurus again wrote the encyclopedic work *De rerum natura (On the Nature of Things)* as part of his programme for reforming the education of the clergy. Although Isidore of Seville, the Venerable Bede and Alcuin were among the best-educated people of their times, the intellectual communities in which they worked were small and isolated, consisting of monasteries and a few court-based schools (see Carolingian Renaissance).

By the turn of the tenth century, however, perhaps partly as a result of the efforts of Charlemagne and Alcuin, the situation was changing. John Scottus Eriugena, recruited from the British Isles into the Frankish court of Charlemagne's grandson, was able to make use of sources written in Greek. Through Eriugena, many of the ideas of the Neoplatonists, particularly those of the mysterious Pseudo-Dionysius the Areopagite, were imported into the West in Latin translation. Through Eriugena's translation of Pseudo-Dionysius' *De coelesti hierarchia (On Celestial Hierarchy)*, the West inherited its elaborate notion of nine orders of angels (angels, archangels and principalities, dominions, powers and authorities, and cherubim, seraphim and thrones). Though some of Eriugena's work was condemned as heretical in the thirteenth century, and although Pseudo-Dionysius was later shown not to have been Paul's Athenian disciple as had been thought (but rather someone living after the time of Proclus), nevertheless an elaborate taxonomy of angels was accepted as an intrinsic part of the cosmos throughout the later Middle Ages. Angels were considered no less real by medieval scholars than neutrinos or quarks are to educated people of the late twentieth century, despite their invisibility to the ordinary eye.

By the year 1000, Gerbert of Aurillac, tutor to the Holy Roman Emperor Otto III, had already travelled to Spain to bring Islamic knowledge to the rest of Europe. Gerbert was perhaps the first person to be able to operate on an

intellectual level comparable to that of Boethius, at least as regards the seven liberal arts (especially the trivium). It was at about this time that something that might be called natural philosophy began to appear in the schools established in cathedrals in urban centers such as Chartres, Paris and Laon. Such natural philosophy might take the form of a creation myth, such as Bernard Sylvester's *Cosmographia*, a work that combined ideas of Genesis with ideas of Plato's *Timaeus* to describe the origin and organization of first the macrocosm (natural world) and then of the microcosm (the human being) (see Bernard of Tours). Some twelfth-century authors, for example William of Conches, attempted to give an explicitly natural explanation of the cosmos, albeit within an assumed Christian context. The general world picture that these Platonistic Christian authors passed on to the natural philosophers of later centuries was one in which God first establishes and then maintains order in the cosmos, so that there is a natural design which natural philosophers may study using purely human, rational and empirical means.

Before the rise of the universities in the twelfth century, then, there was a well-established intellectual culture in the Latin West, largely dependent on clergymen but extending also to a few nuns and a few of the aristocratic laity of both sexes. Apart from the subjects of elementary education, manuscripts might concern religious topics, medicine (including compilations about medical plants), animal lore (bestiaries), basic astronomy for calendrical purposes (*computus*), or astrology and meteorology. Clerical readers might make use of animal lore in preparing sermons, taking examples of courage from lions or of compassion from pelicans and the like.

In the twelfth century, the available writings on nature were suddenly vastly increased by a spate of translations from Arabic to Latin, either of Greek works that had previously been translated into Arabic, or of original Arabic works (see Translators; Islamic philosophy: transmission into Western Europe). Thus in the late twelfth and early thirteenth centuries, as the universities were beginning to develop, philosophers suddenly had access to the natural philosophical works of Aristotle, which had previously been unavailable in Latin. Although the works of Aristotle were over fifteen hundred years old by the year 1200, they represented a level of natural philosophical sophistication well above what had been available in the earlier Middle Ages. They were therefore highly attractive to the clerical scholars who read them despite the fact that they contained ideas at least superficially contradicting Christianity, such as Aristotle's purported proof that the universe must always have existed. Initially, popes and bishops tried to forbid the reading or teaching of Aristotle's natural works, but by the mid-thirteenth century these works became the basic teaching texts at the University of Paris and other universities. In the later thirteenth century, Albert the Great, Thomas Aquinas, Robert Grosseteste and Roger Bacon were among the first Latin commentators to lecture to university audiences Aristotle's *Physics*, *On the Heavens* and other natural works. In doing this, they often made use of translations of the Arabic commentaries of Averroes (see Ibn Rushd), composed in Muslim Spain in the previous century. They also used Latin translations of the works of other Islamic and Jewish authors such as al-Kindi, al-Farabi, Avicenna (see Ibn Sina) and Maimonides.

Finally, there was the study of subjects such as astrology and alchemy, which were at least peripherally related to natural philosophy but were not part of official university curricula. Both these disciplines made considerable use of Aristotelian ideas of the cosmos, celestial influences on earth, the elements, chemical change and so forth. The situation is confused by the fact that there are works on astrology, alchemy and even magic attributed to prominent university scholars such as Albert the Great and Thomas Aquinas. These works, if authentic, cast considerable light on the natural philosophical views of their authors; even if they are not by the individuals to whom they are ascribed, these works can tell us much about the general ambience of medieval natural philosophy, and particularly about the perceived connection between the heavens and the earth.

2 Natural philosophy in medieval universities: sources

In the thirteenth and fourteenth centuries, natural philosophy was done most directly in the form of disputing questions arising from Aristotle's natural works. Although, as has been stated, a distinction was maintained in the medieval university between the discipline of natural philosophy on the one hand and the disciplines of the liberal arts and higher faculties of theology and medicine on the other, nevertheless some natural philosophy, including some of the most advanced and innovative work, was also done under the umbrellas of theology (especially in northern universities) or medicine (especially in southern universities).

The primary sources upon which thirteenth- and fourteenth-century natural philosophers drew were the natural works of Aristotle and later commentaries on these works. Aristotle himself often discussed the views of his predecessors, and his medieval commentators followed him in this practice. Thus a medieval commentator might

contrast Aristotle's views with those of the Presocratics - including Thales, Anaximander, Anaximenes, Heraclitus, Pythagoras, Parmenides, Zeno of Elea, Anaxagoras, Empedocles, Leucippus and Democritus - or he might compare Aristotle's ideas to those of Plato. Additional sources of ideas included medical works, such as those of Hippocrates (see Hippocratic medicine) and Galen among the Greeks as well as various medieval medical authors. Medieval natural philosophers also knew something about the ideas of the Stoics (see Stoicism), the Epicureans (see Epicureanism), the Neoplatonists, including Simplicius and Philoponus (see Neoplatonism), and Roman and medieval Latin authors from Pliny and Seneca to Calcidius, Macrobius, Martianus Capella, Boethius, Isidore, Alcuin, John Scottus Eriugena, Gerbert of Aurillac and various others (see Encyclopedists). Among Islamic authors the most influential were al-Kindi, Avicenna (see Ibn Sina) and Alhazen as well as Averroes (see Ibn Rushd) and his many Islamic predecessors whom Averroes discussed in his commentaries on Aristotle, such as Avempace (see Ibn Bajja). A few Jewish authors, such as Maimonides, were also used.

Although they were not likely to cite them in purely philosophical work, medieval commentators on Aristotle's natural philosophy also knew earlier, specifically Christian writings such as the various works of Augustine and other church fathers, including commentaries on Genesis and discussions of predestination, the nature of the soul, the sacraments and so on (see Patristic philosophy). As medieval theology developed, it not infrequently led to partly philosophical speculations which, in turn, had an influence on natural philosophy. Theological discussions of God's power, eternity, infinity, the Eucharist, the soul and the angels produced results that subsequently fed into the further development of natural philosophy. Thus for example, the idea that in the Eucharist the qualities of the bread and wine are present without inhering in any substance led to the conclusion that it was not self-contradictory that there might be accidental forms that existed independently.

3 Natural philosophy in medieval universities: goals

The purpose of natural philosophy as taught in medieval universities was to understand nature: that is, the created world, or cosmos, and everything contained in it. As indicated above, the materials used by university scholars for their study of the cosmos were the writings of their predecessors, pre-eminently the works of Greek philosophers (especially Aristotle and Plato and their followers), but also Muslim and Jewish philosophers insofar as their works had been translated into Latin, and earlier writers in Latin. It was quite unusual for medieval natural philosophers to draw new empirical information into their work except by reference to common knowledge and daily experience.

Theology, however, did provide what were considered new facts to be taken into account by natural philosophers insofar as they took theology to be a science comprised of truths about the world. For example, theology taught that angels were real created beings; consequently, medieval natural philosophers took angels into account in forming general metaphysical or natural philosophical theories. If angels were thought to be both indivisible and moveable, then natural philosophers might question Aristotle's argument that it is impossible for an indivisible to move.

Natural philosophy, along with the liberal arts, was thus a 'handmaiden' or service discipline to theology, but it would be a mistake to confuse the situation in medieval universities with that found among some fundamentalists today. By and large, intellectual integrity and exactness were hallmarks of medieval university scholars including the members of the theology faculties, who were nothing if not rational. Going as far back as Augustine (and to Philo Judaeus before him), Christian scholars had come to the conclusion that if Christians were not well-educated they could not win the respect of non-Christians in their societies, who were often, as in the case of the Greeks, highly educated themselves. Moreover, Christian scholars wanted to learn the truth about the world in its natural as well as its divine aspects, and they did not expect that true philosophy would contradict true religion. They had not yet imagined a 'warfare' of Christianity and science, such as later occurred between the Copernican view of the universe and the Catholic church in the case of Galileo, or between Darwinian evolution and creationism. Medieval scholars understood that God gave human beings reliable minds and sense organs so that humans could learn about the cosmos, as well as about God's plan for it.

The goal of medieval natural philosophy was therefore to discover the truth about the world for its own sake. Medieval natural philosophy differed from modern science not in being tied to religious dogma and authority, but rather in the fact that it was *not* tied to technological application or economic spin-off. Modern scientific critics sometimes discredit medieval natural philosophy on the grounds that it was not sufficiently experimental or

mathematical, and seems to have spun fantastical theories solely on the basis of cloistered speculation. Medieval natural philosophers might defend themselves against this criticism on the ground that their job was to teach future priests, ecclesiastical or secular administrators, lawyers and physicians for whom scholastic methods were well suited. Had they been asked to teach future engineers, their approach might certainly have taken more mathematical and empirical directions. To ask whether medieval natural philosophers should have had a technological goal is beyond the scope of this article: the relevant point here is that the goal of medieval natural philosophy was knowledge of the world for its own sake and as a sturdy and flexible tool for use in the higher faculties, not for use in technology (the modern Western assumption that rapid technological progress is possible and good is the exception rather than the rule within world history).

4 Natural philosophy in medieval universities: practitioners

Because natural philosophy was mainly a university subject, and because medieval students and faculty were considered to be clergymen of a sort, the practitioners of medieval natural philosophy were almost always celibate men. Rarely and marginally, a work with natural philosophical content was written by a medieval woman, usually a nun - Hildegard of Bingen, for instance, who was the author of books of visions including visions of the cosmos - or by a non-clerical man - for example, the Emperor Frederick II, who was the author of a work on falconry including natural philosophical content.

Modern scholars, writing from Marxist, feminist or third world points of view, have faulted medieval natural philosophy (and medieval scholasticism in general) for its narrowness, arguing that because its study was limited to celibate white Christian men, it represented the interests and biases of only a very small segment of society. Certainly this narrowness may explain why the study of natural philosophy was devoted to a certain kind of knowledge, with no concern for the material well-being of society as a whole. Then as now, however, some authors were motivated by narrow self-interest while others had a more generous point of view. Because the medieval church was a powerful social institution that placed a high value on intellectual inquiry and supported scholars, many highly intelligent men were attracted into the universities and were given the institutional support to devote their entire attention to intellectual matters.

5 Natural philosophy in medieval universities: literary genres

The forms in which medieval natural philosophy was written were mainly determined by the teaching practices of medieval universities. This teaching fell into two main types, the lecture and the disputation. Lectures in natural philosophy most frequently involved the reading (*lectio*) of one of the books of Aristotle, either ‘cursorily,’ simply reading the book rather quickly, or in the more formal ‘ordinary’ fashion, with pauses in which the lecturer explained the structure of the text, emphasized Aristotle’s main points or conclusions, cleared up special difficulties and so on. In a disputation, on the other hand, not only the lecturer but several disputants, often including advanced students, took part. Some disputations were tied to the texts covered in the lectures and concerned questions that arose from the text. One or more individuals (the ‘opponent’) would raise problems about the question, and one or more individuals (the ‘respondent’) would reply. After this had gone on for some time, the master overseeing the disputation would give what he considered to be the correct answer to the question (the ‘determination’), organizing logically the main points that had been made in the disputation, reinforcing the arguments that supported his view and responding to arguments for alternative positions. More rarely there were disputations on more general themes, not closely tied to any one text. One type of disputation detached from texts was the disputation on sophismata (*de sophismatibus*), in which students tried to untangle the possible truth-values of seemingly paradoxical statements, some of which concerned natural subjects such as heating and cooling or the traversal of distances. Contrary to stereotypes deriving from the trial of Galileo in the seventeenth century, medieval university disputants pursued their inquiries with relentless logic and were not constantly looking over their shoulders lest the expression of heretical views might lead to their condemnation. In fact, medieval university disputants were often themselves the authorities whose job it was to determine what was true and what was not.

These oral lectures and disputations sometimes led to written accounts, and masters of arts also occasionally wrote expositions of texts or determinations of questions in advance of lecturing or instead of taking part in oral disputations. There are also marginal glosses and brief expositions on the manuscripts of Aristotle’s natural philosophical works, which formed a large percentage of the medieval natural philosophical textbooks; an example is Robert Grosseteste’s notes or commentary on Aristotle’s *Physics*. Some scholars, such as Albert the Great,

wrote paraphrases of the Aristotelian texts, perhaps to make the meaning clearer. (The Latin translations of Aristotle, either directly from the Greek or indirectly through an intermediate Arabic translation, were often difficult to understand simply because of the wording.) More important in terms of the specifically medieval contribution to natural philosophy were compilations of ‘questions’ on the Aristotelian texts. Written in the standard ‘scholastic’ form, these ‘questions’ began with a question related to the text and then gave arguments for and against a number of possible answers to the question, before going on to the author’s preferred answer. Almost always one finds the question and then one or more ‘principal arguments’ that are opposed to the position that the author will ultimately adopt. Then there are brief arguments for the other side (*in oppositum* or *sed contra*), followed by the ‘determination.’ This determination may begin with clarifications or definitions, then give the preferred answer, put forth objections to this answer and answer the objections. Finally, there are responses to the principal arguments put forth at the start.

In sum, medieval natural philosophy was predominantly studied in medieval universities, based on texts of Aristotle together with a series of later commentaries on the latter’s works. Medieval philosophy began by assuming the truth of the general view of the cosmos advocated by Aristotle, but over time natural philosophers modified this view in many respects, although without overturning it. When the natural works of Aristotle first became available in Latin in the early thirteenth century, they were rejected, most notably at Paris, because of their conflicts with Christianity. Before long, however, Aristotle’s natural works became widely-used textbooks, and their incompatibilities with Christianity provided the grist for repeated disputations and efforts to discover where the truth lay. By the end of the Middle Ages, a few scholastics composed their own treatises on natural philosophical topics (for example John Dumbleton’s *Summa logicae et philosophiae naturalis (Summa of Logic and Natural Philosophy)*, but these almost always dealt with Aristotelian themes (see Logic, medieval).

6 The Aristotelian cosmos

Medieval natural philosophy was therefore predominantly a series of more or less far-reaching variations on the theme of Aristotelian natural philosophy. Basing themselves on Aristotle, with a lesser reliance on Plato, medieval natural philosophers assumed that the natural world or cosmos is finite and spherical, with a spherical earth at the centre surrounded by spherical shells of water, air and fire (with some mixing, especially at the boundaries, such as the surface of the earth). The moon and all the rest of the heavenly bodies are contained in spherical shells of a fifth element called aether, turning in uniform circular motion about the centre of the cosmos, at which the earth is located. Technical astronomy, in order to account exactly for apparent motions of the planets, sun and moon, modified this idea by allowing additional aether spheres that rotated about centres other than the center of the cosmos. Such additional spheres were called eccentrics and epicycles.

For Aristotle, the cosmos ended with the outermost aether sphere (*primum mobile*), which contained the stars and rotated at a rate of approximately once per day, carrying all the other heavenly bodies with it. Outside the *primum mobile* was nothing, not even empty space. Medieval theologians and authors such as Dante in his *Divine Comedy* reconciled this Aristotelian picture with Biblical accounts of heaven and hell by placing hell in the center of the earth and by adding a last, unmoved sphere, the empyrean heaven containing the souls of the blessed, outside the *primum mobile*, and fourteenth-century theologians also supposed that God was outside the cosmos. Medieval technical astronomers also sometimes added an extra empty sphere to account for the precession of the equinoxes, the apparent motion relative to the stars of the points at which the sun crosses the celestial equator. The *primum mobile* could then be thought to be an empty sphere rotating approximately once a day, inside of which would be the sphere of the fixed stars, carried around by the *primum mobile* outside it but with its own proper rotation in the opposite direction about a different axis, with a period of about 26,000 years.

Following Plato and Aristotle, medieval natural philosophers assumed that everything in the cosmos (or everything except the movers of the heavenly spheres) is composed fundamentally of prime matter, which has no characteristics of its own, and forms, which give characteristics to matter. The technical term for an individual thing existing in the cosmos was ‘substance’; for example, a human being is a substance, a tree is a substance, a stone is a substance and so on. Each substance has a substantial form that makes it what it is or gives it its so-called ‘essential’ characteristics. For example, the substantial form of human beings makes them rational animals: anything that is not rational or not an animal is not human. Each substance also has many so-called ‘accidental’ forms such as colours or temperatures. These accidental forms happen to characterize a substance, but

are not essential to it, as it is not essential for a human being to have blue eyes or even five fingers on each hand.

Following the ideas of Aristotle's *Physics*, medieval natural philosophers also took it for granted that all or most things in the cosmos move, understanding by the term 'motion' not only local motion but also alteration (or change of quality) and augmentation and diminution (or change of size). The task of the natural philosopher was to explain or give the causes why the bodies in the cosmos move or change as observed. Thus medieval natural philosophy tried to answer such questions as, why do the sun, moon and stars move through the sky as they appear to move? Do animals move themselves, or is there an external cause of their motion; for instance, the food they see in front of them? How are metals formed? How do animals reproduce? How does nutrition occur?

The sorts of causes that natural philosophers looked for were usually forms, either substantial forms or accidental forms. In the terrestrial realm, from the centre of the earth up to the sphere of the moon, there were four elements - earth, water, air and fire - and many compound bodies formed by the interaction of these elements, including minerals, plants, animals and humans. Each of the terrestrial elements was thought to have two basic qualities: earth is cold and dry, water is cold and wet, air is hot and wet, fire is hot and dry. If one asked, 'Why does water evaporate and become steam or air?' the answer might be that fire, which is hot, heats the water so that its coldness is changed to warmth, with the result that the cold and wet water becomes hot and wet air. When they considered that an element such as water has a substantial form that makes it water as well as basic qualities that make it cold and wet, then natural philosophers might debate whether it is the heat of the fire or the substantial form of the fire that heats the water. Assuming further that the first result of heating water is hot water, natural philosophers might try to understand more exactly when and how the hot water changes its substantial form to become air. The usual answer was that the substantial form does not change until the very end of the process (when, in our terms, evaporation occurs): a less common answer was that, in reality, water and air have the same substantial form, differing only in their accidental qualities.

When the elements interacted to form minerals, plants or animals, questions about changes of substantial form became more serious. Gold, for instance, was assumed to have a substantial form that made it gold as well as being generated by a combination of earth, water, air and fire or by interactions of hot, cold, wet and dry. One not uncommon Platonic or Neoplatonic model was that the terrestrial elements interacted up to a certain point and then influences from the celestial realm, the planets and stars, led to the introduction of the substantial form into the prepared matter. For those thinking in a specifically Christian context, the idea was that God sometimes chooses to act using the heavenly bodies as instruments. In the case of humans, the rational soul might be supposed to be introduced into the embryo in this way, leading to 'quickening' and noticeable motion within the womb. This would be the point in time at which the embryo became a human being. This whole scheme provided a rationale for astrology, the study of the configurations of the heavenly bodies to predict a person's nature and likely fortune, since the exact configuration of the heavens at the time of the introduction of the rational soul would likely affect its nature at least accidentally.

In considering the whole realm of compound bodies on the surface of the earth, medieval natural philosophers followed Aristotle and Greek medical theorists in assuming that there are levels of souls or faculties active in living things, where a 'soul' is understood as a source of motion or activity in the substance or thing (see Hippocratic medicine). Plants have a 'nutritive soul' that explains their growth and reproduction; animals have a 'sensitive soul' that explains their motion and sensation as well as their growth and reproduction; and humans then have a 'rational soul' that explains their ability to think as well as all of the lower functions. It was a matter of disagreement whether each living thing has only one substantial form, which is the source of all its motions or actions, or whether the higher living things have forms that make them bodies and also souls. In more physiological or medical contexts, philosophers also made use of the concept of 'spirit' (*pneuma*), with the idea that the soul, conceived as pure form, uses spirit, conceived as the thinnest possible gas-like stuff, to move the body, whether in nutrition, sensation or local motion.

In the inanimate realm (things without souls of any sort), forms were also used to explain the natural motions of the elements and compound bodies. The elements earth and water were understood to be heavy, that is, to have a form called 'gravity' which leads them to move downward whenever this is not prevented or whenever they are not as close as possible to the centre of the cosmos. Likewise air and fire were supposed to be characterized by lightness or 'levity' as a form, leading them to move upward whenever they are below their natural places and not

hindered from moving higher. Thus it might be an internal characteristic (form) of a heavy or light body that explained its downward or upward natural motion, toward or away from the centre of the cosmos. The cause of gravity was not ‘attraction’ between bodies across empty space, as it would later be understood following Newtonian physics. For an Aristotelian, there is no empty space, and, even if there were, there could be no action at a distance without any intermediary. From the Aristotelian point of view, the only cases of apparent action at a distance between inanimate bodies were the attraction of magnets for iron and electrostatic attraction or repulsion, as between amber and chaff. Even these phenomena were explained without supposing action at a distance between inanimate bodies; instead, bodies were supposed to multiply forms of a sort (so-called ‘species’) into the medium surrounding them and up to the other bodies on which they might act.

Occasions on which elements, or compounds in which given elements were predominant, did not move in their natural directions (heavy bodies downward and light bodies upward) were also explained by medieval natural philosophers along Aristotelian lines, arguing that there must be an external force causing these elements or compounds to move in an unnatural direction and that this external force must be in contact with them. This idea followed obviously from everyday experience: loaded carts, for instance, do not move along the road unless some person or animal is in contact with them and pulls or pushes them. In the later books of the *Physics*, Aristotle had broadened this common conception to argue that everything that is moved is moved by something else (*omne quod movetur ab alio movetur*). In an apparent inconsistency with what he said elsewhere about souls being sources of motion in substances that have them, Aristotle argued in the *Physics* that living things and even elements in their natural motions have outside movers. Medieval Christian Aristotelians sometimes resolved this apparent inconsistency by concluding that only human beings, because of their free will, can act independently of outside forces.

In the celestial realm, it was supposed to be natural for aether to move in a circle around the centre of the universe. Apparently there was nothing to resist this motion since, according to Aristotle, it had been going on forever with no change of velocity whatsoever. An ox pulling a cart becomes fatigued because of the resistance to its pulling and, after a time, slows down. The celestial movers, however, must experience nothing similar since their motion continues unretarded for time without end. Because what happens on earth and what happens in the heavens are quite different, the explanation for the motion of the heavenly spheres is different from the explanation of terrestrial motion. To make a rough comparison, the movers of the heavens were supposed to move the celestial spheres in the way that hay causes a horse to move toward it, that is, by arousing in the moved body the desire to move. Unlike hay, however, the movers of the heavenly spheres were supposed to be immaterial, as Aristotle had argued they must be if they are to remain unmoved themselves; they must be so-called ‘intelligences’ or ‘separated substances’ (separated, that is, from matter). In more thoroughly Christianized versions of these theories, the celestial intelligences were sometimes identified as angels. In a view that was condemned by the Bishop of Paris in 1277, the celestial spheres were supposed to have their own souls, united to their matter, by which they perceived the separated substances and were therefore motivated to rotate. While this view of souls of the spheres helped to complete the analogy between the cause of their rotation and the cause of the motion of animate beings such as animals and humans, it was opposed to the Christian conception of the cosmos; if it were true, it would seem to imply that the celestial spheres were the most perfect beings in the cosmos, more perfect than humans because their matter was more perfect, although they were alike in having rational souls.

However, if in the Aristotelian cosmos the heavens were thought to be very different from the terrestrial realm below the sphere of the moon, the two realms were not disconnected. Influences from the heavens upon the earth were supposed to occur constantly, through the agency of light or other similar forms. In the Aristotelian explanation of light, a light source (*lux*) does not send out particles or anything else material; rather, the light source affects the medium immediately surrounding it, producing in it an illumination (*lumen*), which in turn causes the next part of the medium to light up, and so on. Thus no matter is moved in the spreading of light, but rather a form reproduces itself in decreasing degrees in successive contiguous parts of a transparent medium. In this model of light, other forms (for example, the form that causes magnetism) might be thought to reproduce themselves in contiguous bodies. This process, called by the generic name ‘the multiplication of species’, occurred constantly throughout the cosmos. In this usage, the word ‘species’ referred to forms that copy the form that causes them while not being entirely identical or not having identical power, like images in a mirror (*speculum*). From the time of the Greeks, optics, or the geometrical study of the ways in which light propagates itself, had been highly

developed, including studies of reflection, refraction and the decrease in intensity with distance. In the later Middle Ages, the model of optics was widely presupposed in the understanding of how other forms, such as heat and cold, might act on neighbouring bodies. Some alchemists believed that the substantial form of gold might under proper circumstances multiply itself in a similar way, transforming other metals into gold. Pharmacists likewise assumed that drugs act on the body not through the material of the drug incorporating itself into the human body (as happens with food), but through the substantial and accidental forms of drugs heating, cooling, moistening or drying the tissues with which they came into contact, or by the drug multiplying some other 'species' or effect of a specific form into parts of the body.

The medieval Aristotelian cosmos, then, was almost the opposite of the universe of the ancient atomists (see Atomism, ancient). Whereas for the atomists the universe is infinite, for Aristotelians it is finite. Whereas for the atomists the universe is made up of particles alike in their matter separated by empty space, for Aristotelians bodies differ from each other intrinsically by their substantial and accidental forms, not only by their size, position and motion; moreover, empty space is impossible. The atomists further theorized that fundamental particles have a size but cannot be cut into pieces ('atom' means uncuttable in Greek), while for the Aristotelians there is no limit to divisibility; no matter how finely something has been divided, it can still be divided further. This was expressed by saying that matter is potentially but not actually infinitely divisible; in other words there is no limit to the number of times one can divide a body into smaller and smaller pieces (this is the potential infinity), but one could not actually finish dividing the body infinitely many times (to finish an infinite process was considered to be a self-contradiction).

7 Self-consciousness of philosophers and the philosophic life

This, then, was the basic view of the cosmos accepted by medieval natural philosophers. From about the middle of the thirteenth century, when Aristotle's books were adopted as the textbooks for natural philosophy, philosophers began to clarify and suggest modifications in the received Aristotelian view. Sometimes obscure even in Greek, these texts had become far more difficult in the process of translation, especially when there had been an Arabic intermediary between the Greek and Latin; the differing vocabularies and grammatical structures of Arabic and Greek required many modifications in order to translate as literally as possible from Greek to Arabic, and with similar problems again occurring during the later translation from Arabic to Latin.

The difficulty of the Aristotelian texts was further compounded when one asked whether or how they fit with Christian faith. What should a person teaching natural philosophy do with the texts in which Aristotle ostensibly proves that the world has always existed, when Genesis says it was created? There were also the commentaries of Averroes who, although he was a monotheist, could not be expected to adhere to specifically Christian beliefs (see Ibn Rushd). Commentators on Aristotle often held degrees in arts but not in theology (though they might simultaneously be students in a faculty of theology). Lecturers on philosophy were not authorized to discuss specifically theological points in the classes of the arts faculty, but they were taken as authoritative on purely natural issues.

In these circumstances, Boethius of Dacia at the University of Paris argued that a philosopher should always resolve every philosophical difficulty solely from the point of view of philosophy. In his view, this was a matter of disciplinary integrity. Aristotle had said in the first book of the *Physics* that a geometer need not argue with someone who denies his principles or axioms; if a person denies one of the axioms of geometry, it will be impossible to prove something to him using those axioms or anything better known than the axioms. So too, Aristotle said, a physicist need not argue with someone such as Parmenides, who denies that motion occurs. That all or some things move, Aristotle argued, is the most obvious fact of physics, so that if a person denies that things move, it will be impossible to find a more obviously true principle on which to build a physical proof that motion occurs. In a similar way, each discipline has fundamental principles that are not proved but are taken as obvious for the purposes of that discipline, and on the basis of these principles, the practitioners of that discipline reason to conclusions. When people are practising a given discipline, they can and should assume that its principles are true.

Arguing on this basis, Boethius of Dacia claimed the right to conclude, when he was working in natural philosophy, that the world had no beginning because, rationally speaking and accepting the principles of Aristotelian natural philosophy, Aristotle proves that the world, if it exists at all, must be eternal or perpetual: something does not come from nothing; something is not caused by nothing and so on (see Eternity of the world,

medieval views of). On the other hand, as a Christian, Boethius of Dacia believed that the world was created by God as told in the book of Genesis; but, in his opinion, this did not affect the cogency of Aristotle’s philosophical argument for the eternity of the world. When Boethius was speaking as a natural philosopher, he was speaking not as a Christian but as someone who accepted the principles of natural philosophy.

In the furore that these views caused among Boethius of Dacia’s contemporaries, some thought that he could not and should not assert, even when doing natural philosophy, something that contradicted Christian faith and that he should be disciplined for teaching such a heresy. In reply, Boethius tried to explain why he should be able to assert without blame, when acting as a philosopher, conclusions contradicting Christian beliefs that he himself shared. In the excitement of defending his position, Boethius added to his armament many claims about the joys of the philosophical life, such as that no one lives a higher or happier human life than the philosopher.

In opposition to Boethius of Dacia, Thomas Aquinas developed a position allowing for a synthesis or merging of philosophical and Christian views. Arguing that Boethius’ position amounted to claiming that there can be two truths that contradict each other, the truth of philosophy and the truth of Christianity, Aquinas emphasized that there is only one truth and that true philosophy cannot contradict true Christianity. In the view of knowledge proposed by Aquinas, the truths of philosophy and the truths of faith are partially overlapping and partially separate. There are some things we know only by reason, some things we know only by faith and some things we know both by reason and by faith. That there are four terrestrial elements, for instance, we know only by natural philosophy and experience of the physical world, and that God is a trinity of Father, Son and Holy Ghost, we know only by faith; but that God exists, as the creator, mover and highest good of the universe, we know both by reason and by faith. Thus Aquinas proposed several cosmological and teleological arguments, generally founded on natural philosophy, which he claimed prove rationally the existence of God (see God, arguments for the existence of).

With regard to Aristotle’s supposed proof of the eternity of the world, Aquinas adopted the strategy of Maimonides’ *Guide to the Perplexed*, arguing that Aristotle’s proof is not demonstrative. Though Aristotle may have thought he had proved that the world is eternal, the argument could be refuted on rational grounds by pointing out that creation is after all supposed to be a supernatural rather than natural act. But, neither can it be proved philosophically that the world was created a finite time in the past. Thus for Aquinas the question of the eternity or newness of the world is philosophically neutral or undecided. Since philosophy leaves the question open, Aquinas could determine on the basis of faith that the world is created, with no inconsistency with natural philosophy.

Thus Aquinas, like Boethius of Dacia, argued that philosophy has an important role to play for the Christian as well as for the non-Christian. By dint of long study, Aquinas became one of the most knowledgeable and skillful Aristotelian philosophers of his day. On the basis of his synthesis of Aristotelianism and Christianity, other thinkers, prominently Dante in his *Divine Comedy*, developed a view of the cosmos that included both Aristotelian and Christian elements.

However, Aquinas’ proposal of a Christian-Aristotelian synthesis did not convince everyone, nor did it survive for long unmodified after his death. In the 1270s, the Bishop of Paris issued two condemnations which included theses put forth by Aquinas as well as by Boethius of Dacia (see Aristotelianism, medieval). In the later of these condemnations, a primary target was those natural philosophers who claimed that even God could not do what was impossible according to Aristotelian physics. If Aristotle proved that a vacuum cannot exist, so said these natural philosophers, then even God cannot make a vacuum. To the contrary, implied the condemnation of 1277, God is not limited by what is possible or impossible according to Aristotelian natural philosophy.

In arguing that the world cannot have had a beginning in time, Aristotle had adopted what has been called the statistical interpretation of modality or of possibility and necessity. On this interpretation, what is impossible never happens, what is necessary is always the case, and what is contingent or possible is sometimes the case and sometimes not. This implies that what is possible must sooner or later occur. As Maimonides reported in his *Guide to the Perplexed*, the *mutakallimun*, in defence of monotheistic religion, had adopted a different conception of possibility, making the possible not what sometimes happens, but what can be imagined without contradiction (see Maimonides).

In the Latin West, John Duns Scotus was the first to make use of the concept of ‘logical possibility’ (*possibilitas logica*), saying that what is contingent is not what is neither necessary nor impossible, but rather such that its opposite could have happened at the very same time that it did. Something is possible if it is not self-contradictory, whether or not it ever exists in reality. Following along these lines, fourteenth-century natural philosophers and theologians often discussed counterfactual cases according to imagination (*secundum imaginationem*). Even if there are no vacuums in the cosmos, they asked, what would happen if God made a vacuum and if a projectile were placed within it: would it move infinitely fast, with a finite velocity, or not at all? Or what would happen if God rotated the cosmos as a whole? Since there would then be no fixed point of reference, how could the rotation of the cosmos be distinguished from rest? In such discussions *secundum imaginationem*, natural philosophers often made a distinction between God’s absolute power (*potentia Dei absoluta*) and God’s ordained power (*potentia Dei ordinata*). God’s ordained power referred to the ways in which God has chosen to create and sustain the universe, as pictured in twelfth-century cosmogonies making use of Plato’s *Timaeus*, with its image of the Demiurge or Craftsman who forms an orderly cosmos out of a pre-existing chaos. God’s absolute power, on the other hand, covered everything that God might have chosen or done, even though God has not so chosen in fact. God chose to make a single cosmos with the earth in the centre, but God could have made more than one cosmos. Although there are no vacua in the universe, if God had wanted to create vacua, God could have done so.

In this distinction between God’s absolute and ordained powers, natural philosophy was understood to focus on the world as it has been formed by God’s ordained power. On the other hand, arguments *secundum imaginationem* or *de potentia Dei absoluta* might be used to help clarify what things are and are not distinct, or independent of each other. So, William of Ockham might argue, if motion or quantity are really distinct things, then God can create motion without any moving body, or quantity without anything that is extended or quantified. If God cannot cause motion to exist without a mobile (the very concept being self-contradictory), so Ockham might argue, it follows that the word ‘motion’ does not refer to anything other than substances or qualities. In this way, arguments *secundum imaginationem* involving God’s absolute power were used to support nominalism or a minimalist ontology without necessarily implying that God actually puts his absolute power into effect as imagined.

Thus in the late medieval understanding, God establishes but is not limited by the laws of nature. The only things that God could not do are those whose existence would be a self-contradiction. God could not make a square circle, because a square circle is logically impossible. God can and does, however, create accidents that do not inhere in any substance: this is physically impossible, but not logically or supernaturally impossible. Although naturally there are never accidental forms where there is no substance, such as whiteness where there is nothing to be white, in the Eucharist God miraculously causes the accidental forms of the bread and wine to persist without inhering in any substance (the substances of bread and wine having become the body and blood of Christ, without Christ’s body and blood having taken on the accidental forms of bread and wine).

The significance of all this for the status of natural philosophy was that nearly everyone in the later medieval university accepted a view that had elements of the views of both Boethius of Dacia and Thomas Aquinas. Aristotelian natural philosophy was understood to describe the cosmos as established by God’s ordained power. One could understand that within the cosmos as it currently exists, creation is impossible, and so Aristotle’s argument for the eternity of the world is valid given the laws of nature as they are currently established. On the other hand, the creation of the world as recounted in Genesis could be understood as an event that occurred not within the laws of nature as currently constituted, but rather supernaturally as the effect of God’s absolute power, the occasion upon which God’s ordering of the world was established. Likewise, miracles could be understood as departures from the laws of nature; which departures, as such, did not show that these laws of nature do not exist. God is the first cause of everything that happens, but, except for creation and miracles, events also have secondary causes that act instrumentally according to the patterns described by Aristotelian natural philosophy.

Thus later medieval natural philosophers found a *modus vivendi* in which they were free to follow the dictates of reason and observation in further developing their natural philosophy. They developed a number of methods and theories that were impressively successful, so that fourteenth-century theologians often adopted the methods of the faculty of arts for their own purposes. At the same time, later medieval theology not infrequently posed new concerns which natural philosophers subsequently took into account. If, according to the theologians, God could create a vacuum *de potentia absoluta*, then natural philosophers considered what implications the existence of a vacuum might have for the basic laws and concepts of Aristotelian natural philosophy. If in the Eucharist there are

qualities not inhering in any substance, then natural philosophers took this possibility into account. If, according to faith, God sends messages to earth using angels, then natural philosophers assumed that angels or separate substances were included among the types of entities that exist and whose properties may be discussed by natural philosophy (in fact, they supposed, the Aristotelian prime movers of the heavenly spheres are angels, even if Aristotle does not call them by this name).

Although in this way there was general agreement among the scholastics about how natural philosophy should operate, the results were by no means monolithic. If all agreed that, on the whole, the cosmos consists of substances made up of matter and form, they did not all agree what should be said, for instance, about the matter of the heavens as opposed to that of the sublunar elements. On each of the many problems that could be raised concerning Aristotelian physics, alternative solutions were proposed. University officials did not require natural philosophers to adhere to a single party line. The Dominicans might favour a position different from that of the Franciscans, and students and masters not belonging to any of the mendicant orders might hold still other positions.

8 Medieval variations on Aristotelian natural philosophy: new methods

Students in the faculty of arts in medieval universities perhaps spent more time studying logic than any other discipline, and it was from logic that later medieval natural philosophy adopted many of its most widely successful and transforming methods (see Language, medieval theories of; Logic, medieval). Because modern science uses mathematics rather than logic as its predominant tool (leaving aside experiment and data collection), historians of science have rarely recognized or understood how logic could play such an important and transformative role in medieval natural philosophy.

Put simply, medieval grammar, logic, natural philosophy and metaphysics together developed scholastic Latin to the point where it could map or model the world as exactly as mathematics does in modern science, albeit without the flexibility to describe very great complexity. This was especially the case for those logicians who took a nominalist or Ockhamist point of view, asserting that of the Aristotelian categories, only substance and quality refer to things existing outside the mind (see Nominalism). The basic idea was that words in propositions stand for objects in the physical world, while the syntax of the proposition indicates exactly the relationships between those objects represented in the proposition's assertion. Thus in one view, in the proposition, 'All humans are featherless,' the word 'humans' stands for all and only existing humans, the word 'featherless' stands for all and only existing featherless things, and the syntax of the sentence asserts the claim that every one of the things for which the word 'humans' stands falls also within the group of things for which the word 'featherless' stands.

This general strategy, known as the theory of the 'supposition' of terms in propositions, was then elaborated to apply to the exact interpretation of the propositions of natural philosophy. Many words, the so-called 'categorematic terms,' were supposed to stand for entities falling within the ten Aristotelian categories, especially for substances and qualities in the outside world or for concepts in the mind. Other words important to natural philosophy were explained to be 'syncategorematic terms' or logical operators, words that do not themselves stand for objects in the external world but rather affect the way that other terms appearing after them in the same proposition stand for things in the world. A given syncategorematic term was then associated with a paired 'exposition', in which a single proposition was shown to be expoundable into two or more propositions, the terms of each of which stood for things in the external world in a more standard way than did the terms of the original proposition.

Thus in the proposition, 'Socrates begins to be white', the term 'begins' was explained to be the sort of term that requires exposition, and the proposition was said to mean either (1) Socrates is not now white and immediately after this he will be white, or (2) Socrates is now white and immediately before this he was not white. Then, depending on the characteristics of the predicate term 'white', the natural philosopher/logician could determine which of the two expositions was the correct one. So-called 'permanent' characteristics, like whiteness, were said to have a first instant of being, but no last instant of non-being at their start, while so-called 'successive' characteristics, like running, were said to have a last instant of non-being at their start, but no first instant of being.

Natural philosophy, then, was understood to be exact talk about the things in the external world and their motions

and changes, and the propositions of natural philosophy were formulated and interpreted to make this exact description possible. In the case of the nominalists (William of Ockham, John Buridan, Albert of Saxony and others), this was associated with a great clarity about and minimization of the number of types of things that were supposed to exist in the cosmos. Following Aristotle's *Categories*, the world was supposed to be filled with individual substances, each of which could be qualified by various accidental forms. All the categories except substance and quality (and possibly also quantity) were supposed to involve only manners of speaking or modes of existence of the primary substances and qualities, not additional entities in the universe; thus time, place, relation, position and the rest were not separate things in the universe that natural philosophy had to deal with. All propositions that referred to time, for instance, could be expounded into propositions involving only substances and qualities and perhaps quantities. Aristotle had defined time as 'the number of motion'. Scholastic natural philosophers following Aristotle could say that, since this is what the word 'time' means, time exists only if there is a body in motion and a mind observing that motion and measuring it or assigning a number to it. (In this view, numbers also are not independently existing things in the universe, but require a mind counting substances.) Understanding that this is what time is could serve in part to solve the problem of whether the cosmos had a beginning in time. The cosmos has existed for all time, it might be said, because when there was no cosmos but only God in existence, there was no motion and hence no time. Time begins when God creates the moving cosmos, and it exists fully only if there is a mind numbering that motion (see Cosmology; Time).

A similar precision concerning the supposition of terms in propositions might be used to help solve problems of the possibility that there is a vacuum or empty space outside the cosmos, because 'space' in Aristotelian physics is an apparently significant term that in fact does not and cannot stand for anything to which its definition applies. 'Space', as used by the atomists, is supposed to be an extension in which there is nothing, but according to the medieval understanding of Aristotle, extensions can only be extensions of things; of substances or, in the special case of the Eucharist, of qualities. If it was supposed that God, according to God's absolute power, could create an empty space, that it was not a contradiction in terms, then it was typically concluded that, even so, there would be no extension there, or only an imaginary extension, because only bodies are extended. Even if God was supposed to be in infinite empty space outside the cosmos (as Thomas Bradwardine and Nicole Oresme both suggested), this did not necessarily imply that there would be extension there because God was understood to be wholly present at every point, not extended with one part in one place and another part in another. Just as God's existence 'before' the creation of the cosmos did not mean that there was time before creation, so God's existence 'outside' the cosmos did not mean that there was real space or extension there.

If the most widespread methodological innovation of medieval natural philosophy was the application of the precision of supposition theory, natural philosophers did also make progress in the application of mathematics. In an influential application, Thomas Bradwardine, writing at Oxford in 1328, found a new way to apply the Euclidean theory of ratios as it had been applied to the understanding of musical harmony, to describe the ratios of forces, resistances and velocities in motions. This innovation was so pleasingly apt, appearing very simple yet overcoming important drawbacks of the more authentically Aristotelian view, that it was adopted by nearly everyone. Paired with this innovation in the understanding of the relation of motion to its causes came progress in the exact mathematical description of motion in terms of its effects in the traversal of space, heating, change of size and so on. Corresponding to distances traversed in space, the concepts of 'latitude' and 'degree' were developed to measure intensive changes or the so-called intension and remission of forms. In later decades, the disputations on sophismata that had previously been used at Oxford to demonstrate students' abilities to apply the rules of logic were expanded to involve the new uses of mathematics as well as logic or, more rarely, grammatical theory. From this came the work of authors such as Richard Kilvington, William Heytesbury, Richard Swineshead and the other Oxford Calculators (see Oxford Calculators). Absolutely typical of later medieval natural philosophy and theology was the widespread use of what have been called 'analytical languages' or 'conceptual algorithms', that is, standard patterns of analysis repeatedly used to solve almost any problem. These 'analytical languages' included the Bradwardinian theory of the ratios of velocities in motions, the analysis of first and last instants, and analysis in terms of maxima and minima.

In their commentaries on Aristotle's *Posterior Analytics*, medieval natural philosophers were clear that the starting point for natural philosophy is experience. One starts from observation and works back to find the causes of the effects observed, demonstrating that (*quia*) the causes exist. Natural philosophy as a demonstrative science was

supposed to be complete when the philosopher could start from the causes and demonstrate why (*propter quid*) the effects as originally observed occur. However, if medieval natural philosophers believed in empiricism, they did not believe it was their role to actually conduct observations, let alone experiments. In practice, what medieval natural philosophers did was to try to perfect Aristotelian natural philosophy, making the meaning of its propositions more exact through logic and arguing the merits of various interpretations and modifications of Aristotle through formal public disputations.

9 Medieval variations on Aristotelian natural philosophy: traditions and research programmes

Our current knowledge of medieval natural philosophy has been built up in the twentieth century, for the most part through the combined efforts of historians of science, theology and philosophy. In the last twenty years, important work relevant to the history of medieval natural philosophy has also been done by historians of logic. From the perspective of the history of science, the original motivation, following the groundbreaking work of Pierre Duhem (1985), was to show how the roots of many of the ideas of early modern science could be found in the Middle Ages. For example, the medieval idea of impetus was seen as leading to the early modern idea of inertia, fourteenth-century analyses of uniformly accelerated motion were seen to foreshadow Galileo's analysis of balls rolling down inclined planes (see Galilei, Galileo), and medieval ideas of God's omnipresence were seen to have contributed to Newton's conception of absolute space (see Newton, I.).

In contrast to historians of science, some historians of theology have taken an interest in the history of medieval natural philosophy insofar as it interacted with theology, contributing, for example, to the medieval Christian-Aristotelian synthesis and to the subsequent threat to this synthesis posed by the Copernican thesis that the earth rotates and orbits the sun (see Aristotelianism, medieval; Copernicus, N.). In telling the story of medieval natural philosophy, some historians have taken Aquinas' Christian-Aristotelian synthesis as the high-water mark of medieval Christian philosophy, portraying the nominalist path as a falling away from or dissolution of this synthesis. On the other hand, some historians of the Reformation have taken William of Ockham as the hero of medieval natural philosophy, and have portrayed his nominalism or preference for a minimalist ontology as a fortunate paring away of the overdevelopment of previous scholastic thought. The theological position known as 'voluntarism' has been seen as equally salutary. While Aquinas thought he could reason how the cosmos must be on the grounds that God, as the highest good and all powerful, must have done things in the best possible way, the voluntarists argued that God had a choice, that there were many more things God could have done by his absolute power than he chose to do by his ordained power. If, according to the voluntarists, humans cannot reason what God must have done, they must instead observe the world as it actually is to determine how God in fact chose to create it. Thus, it is suggested, voluntarism in theology led to empiricism in science, and Ockham led to Copernicus and Galileo.

By the sixteenth century, natural philosophers often described their predecessors as followers of the realist way (*via realium*) or followers of the nominalist way (*via nominalium*), but thirteenth- and fourteenth-century natural philosophers less commonly labelled themselves according to philosophical schools. On the other hand, the Dominican and Franciscan orders ran their own houses of study, and a Dominican or a Franciscan friar would likely have studied a somewhat different curriculum before appearing on the scene at Oxford, Cambridge or Paris. Early on, the Dominicans adopted Thomas Aquinas as their intellectual model and so upheld the theory of the unity of the substantial form, that each substance is composed of a substantial form inhering directly in prime matter and that there are no intermediary forms, such as Averroes' 'indeterminate dimensions' (*dimensiones interminatae*) preparing the matter to receive a substantial form.

Some recent historians question the validity or usefulness of categorizing medieval thinkers as nominalists, terminists or Ockhamists. They have also claimed for earlier and less well-known thinkers many of the ideas previously associated particularly with Ockham, and have questioned whether nominalism was as important in the fourteenth century as earlier historians believed. Similarly, some recent historians have questioned the usefulness of the term 'Averroist,' previously applied to medieval natural philosophers to signify either philosophers who followed Averroes' opinion on certain questions - for instance, the question of the nature of the human soul - or philosophers such as Boethius of Dacia who chose to emphasize a purely natural or secular approach without obvious Christian modifications (see Averroism). The usefulness of labels such as 'nominalist' or 'Averroist' varies depending on where one's attention is directed, whether to issues of logic, psychology or theology.

The organization of medieval natural philosophy into schools and trends is also made more complicated by the fact that it was not common for medieval philosophers to claim originality. Someone such as Roger Bacon, who was quick to criticize his contemporaries for what he considered their ineptness, was the exception rather than the rule. Not only did scholastics generally not claim originality, but there were a number of scholastic practices that tended to further obscure their differences. To begin with, the same tools of logic and mathematics - the same analytical languages - could be used by individuals of very different theological persuasions. In commenting on Aristotle, many authors claimed that they were only describing and not advocating the opinions of Aristotle and Averroes. They said that they had recited the arguments for a particular point of view for the sake of (their own or the students') exercise, and not because they necessarily held them to be persuasive, and they often argued that more than one position on a given issue might be 'probable'; that is, one could develop a respectable argument on either side of a disgreement, and no one could demonstrate that one and only one solution was correct. Some texts existed as handbooks to prepare students for obligatory disputations, so they include the source arguments for alternative positions that a student might try to defend.

Sometimes church leaders advocated a sort of decorum so that clergymen would not be seen by the laity to disagree, but this did not apply in general to discussion of natural philosophy within the university because it could be assumed that these would not spill over into public consciousness. Within the university, then, scholars did disagree over natural philosophy issues, but this might not attract much attention unless the given issue had repercussions for theology and individual thinkers were much more likely to fall into camps over differences of opinion in theology than in natural philosophy.

In sum, because natural philosophy was rarely a life or death matter in the medieval university and because the answers to many questions really did remain open, many individual natural philosophers could present views that were somewhat tentative or that evolved over time. On the other hand, if a modern historian follows the discussion of a particular point over time, there is often a definite trend and progress in the solutions given, with some previous difficulties resolved to general agreement. Some of the most prominent commentaries on Aristotle have been studied, but many anonymous or poorly labelled commentaries on Aristotle's natural works still lie unstudied in manuscript form. Historical conceptions of the trends in medieval natural philosophy are likely to continue to evolve. John Duns Scotus seems to have been a pivotal thinker for many natural philosophical topics, even though his influence was exerted through commentaries on Peter Lombard's *Sentences* rather than through commentaries on Aristotle. Walter Burley has been labelled an Averroist and a realist in contrast to Ockham's nominalism, but Burley's position remains unclear, perhaps because there is no modern group such as the Dominicans or Franciscans that takes him as a special ancestor. Depending upon the perspectives of modern historians, new images of medieval natural philosophy can be expected to emerge in the future.

Natural theology

Natural theology aims at establishing truths or acquiring knowledge about God (or divine matters generally) using only our natural cognitive resources. The phrase 'our natural cognitive resources' identifies both the methods and data for natural theology: it relies on standard techniques of reasoning and facts or truths in principle available to all human beings just in virtue of their possessing reason and sense perception. As traditionally conceived, natural theology begins by establishing the existence of God, and then proceeds by establishing truths about God's nature (for example, that God is eternal, immutable and omniscient) and about God's relation to the world.

A precise characterization of natural theology depends on further specification of its methods and data. One strict conception of natural theology - the traditional conception sometimes associated with Thomas Aquinas - allows only certain kinds of deductive argument, the starting points of which are propositions that are either self-evident or evident to sense perception. A broader conception might allow not just deductive but also inductive inference and admit as starting points propositions that fall short of being wholly evident.

Natural theology contrasts with investigations into divine matters that rely at least in part on data not naturally available to us as human beings. This sort of enterprise might be characterized as revelation-based *theology, in so far as the supernatural element on which it relies is something supernaturally revealed to us by God. Revelation-based theology can make use of what is ascertainable by us only because of special divine aid. Dogmatic and biblical theology would be enterprises of this sort.*

Critics of natural theology fall generally into three groups. The first group, the majority, argue that some or all of the particular arguments of natural theology are, as a matter of fact, unsuccessful. Critics in the second group argue that, in principle, natural theology cannot succeed, either because of essential limitations on human knowledge that make it impossible for us to attain knowledge of God or because religious language is such as to make an investigation into its truth inappropriate. The third group of critics holds that natural theology is in some way irrelevant or inimical to true religion. They argue in various ways that the objectifying, abstract and impersonal methods of natural theology cannot capture what is fundamentally important about the divine and our relation to it.

1 A strict conception of natural theology

An influential traditional understanding of natural theology is based on a model of theoretical inquiry derived from Aristotle's account of demonstrative science (see Aristotle §6). The model of demonstrative science describes the logical structure of the truths comprising a given area of theoretical inquiry and the corresponding epistemic structure of the beliefs one has when one has attained theoretical knowledge of that area. On this model, theoretical knowledge is constituted by two sorts of truths: those that are basic or fundamental and those that are dependent on them. Truths of the first sort are facts whose nature is such that they are open to our immediate cognitive gaze. Our knowledge of them consists in our having direct access to or awareness of them, and so they can be thought of as *evident*. They are self-evident if they are accessible to us in virtue of being immediately present to our strictly intellective capacities, or evident to sense perception if they are accessible in virtue of being immediately present to our sensory capacities. When we are directly aware of evident truths in either of these ways, we are epistemically justified in holding them just in virtue of our immediate grasp of their truth. Truths of this sort are epistemically privileged in the sense that one's epistemic justification for holding them is independent of one's justification for any other truths one might happen to hold. They can suitably ground other sorts of knowledge because they require no epistemic ground beyond themselves.

The second sort of truths constitutive of theoretical knowledge in demonstrative science are those derivable from the basic truths by means of demonstrative proofs or deductively valid arguments. These truths are accessible to us by virtue of our capacity for discursive reasoning. In so far as they are known as conclusions of demonstrative proofs they are epistemically dependent, mediated by our awareness of the truth of the relevant premises and the validity of the relevant inferences. We are inferentially justified in holding these truths by virtue of our having derived them in appropriate ways from truths we are independently and non-inferentially justified in holding.

Conceiving of natural theology as a kind of demonstrative science allows us to characterize it precisely: it consists

of truths about God which are either (1) self-evident or evident to sense perception, or (2) derived by deductively valid proofs the (ultimate) premises of which are self-evident or evident to sense perception. Thomas Aquinas (§14) is perhaps the most famous Christian theologian to develop Aristotle's account of demonstrative science and adapt it to theological inquiry. His famous proofs for the existence of God (the so-called five ways) and his arguments establishing such truths as that God is one, immutable and eternal - his proofs for what he sometimes calls the preambles of faith - are paradigms of natural theology understood as an Aristotelian demonstrative science (he himself prefers to call this enterprise divine science). Aquinas' influential articulation and development of this model of natural theology in the opening sections of his two great theological works, *Summa theologiae* and *Summa contra gentiles*, have made this a dominant conception of that enterprise.

Because its method - deductive argument - is clear and subject to precise and well-understood standards, intellectual inquiry that conforms to the model of demonstrative science is open to the sort of rigorous assessment and evaluation crucial to theoretical objectivity. Moreover, when successful, demonstrative science offers for its results the strongest sort of certification possible. By deriving its conclusions from evident truths by means of necessarily truth-preserving forms of reasoning, a demonstrative science guarantees their truth; we can be certain of them and can claim to have conclusively established them. But these virtues are purchased at a price: a demonstrative science's criteria for admissible data and methods are very strict. Indeed, few philosophers today are sanguine about the prospects of satisfying them outside the realms of logic and mathematics.

2 A broader conception of natural theology

Philosophers have always recognized the importance of arguments that fall short of the paradigm of demonstrative proof - that is, arguments that carry epistemic weight but in some way fall short of being utterly truth-guaranteeing. Following a long tradition, we might call arguments of this sort dialectical arguments. The criteria for good or acceptable dialectical arguments will be more generous than those definitive of demonstrative science. On the one hand, dialectic allows as data propositions that we have some appropriate degree of epistemic justification in believing, though they need not be evident either to reason or sense perception. On the other hand, dialectic admits the use of methods of reasoning other than deduction. It allows inductive reasoning broadly conceived - enumerative induction, probabilistic reasoning, argument from analogy, inference to the best explanation and so on. These requirements on the data and methods of dialectic mean that dialectical reasoning might fall short of demonstrative proof in any of three ways: by having evident premises but lacking a deductive argument form; by having a deductive argument form but lacking evident premises; or by lacking both evident premises and a deductive argument form. Of course these specifications of the data and methods of dialectic are imprecise, and philosophers might well disagree about what propositions are admissible as data (that is, have an appropriate degree of justification) and whether certain particular inductive arguments are strong or weak.

Our engaging in inquiry using only methods and data satisfying the criteria of dialectical reasoning requires us to use nothing beyond our natural cognitive resources. Hence, we ought to acknowledge a corresponding natural theology - dialectical natural theology - that consists in philosophical investigation, of the sort allowed by dialectic, into divine matters. We might call the genus of which strict, demonstrative natural theology and dialectical natural theology are species *broad* natural theology. The practitioner of broad natural theology will attempt to establish truths or acquire knowledge about God using deductive or non-deductive arguments the premises of which are evident or justified to some appropriate degree.

Two important contemporary projects in the philosophy of religion demonstrate some of the different ways natural theology might extend beyond the limits of the strict conception. In *The Existence of God* (1979), Richard Swinburne develops inductive versions of the traditional proofs for God's existence and treats theism as a theoretical hypothesis that claims to offer the best explanation for certain phenomena in the world. Swinburne shares with the strict natural theologian the aim of providing good arguments for the truth of certain theological propositions, in particular that the theistic God exists. But he rejects strict natural theology's requirement that limits the natural theologian to arguments satisfying the strict criteria of demonstrative proof, relying instead on techniques and standards derived from recent developments in the philosophy of science and the logic of probability.

By contrast, philosophers such as Alvin Plantinga and Nicholas Wolterstorff have objected to what they see as the epistemological assumptions underlying both strict natural theology and the work of many practitioners of broad

natural theology. Reformed epistemology, as they call it, challenges the view that establishing or defending the rationality of belief in God requires the development of arguments, whether strictly or broadly conceived, for certain theological propositions. They claim that it can be rational to believe in God even if one has *no* evidence for God's existence (see Plantinga and Wolterstorff 1983). Despite this seemingly bold denial of the need for evidence of the sort natural theology might provide, Reformed epistemology does not reject traditional natural theology's general aim of securing appropriate epistemic grounding for certain theological propositions; it rejects only its understanding of what can constitute appropriate grounding. Reformed epistemology allows that belief in God can be properly basic, that is, that the belief that God exists (and other religious beliefs) might appropriately be included among the starting points or data of natural theology. It is therefore a particular kind of defence of the epistemic rationality of our belief in God, and so a kind of broad natural theology (see Religion and epistemology §§1-3.)

Broad natural theology is not a new phenomenon. It has a long history and includes among its practitioners some of the best-known representatives of strict natural theology. Aquinas, for example, recognizes that some theological truths can be established by means of what he calls merely probable, persuasive or dialectical arguments. John Locke (§7), too, allows that reasoning about theological matters that depends solely on our natural faculties can depend on probabilities as well as on necessary reasoning.

3 Reason, revelation and faith

A strict conception of natural theology provides grounds for a clear distinction between natural and revelation-based theology. This is because revelation-based theology, in so far as it is based on divine revelation, is ultimately based on someone's testimony (God's, a divinely authorized agent's or that of historical witnesses to revelatory events). But no proposition whose epistemic grounding essentially involves testimony is either evident or strictly demonstrable. Hence, parts of revelation that are accessible only because they have been revealed are inaccessible to the strict natural theologian and belong exclusively to the domain of revelation-based theology. (The Christian doctrines of the Trinity and the Incarnation have been taken to be paradigm examples.)

Augustine (§11) and the long line of thinkers who have followed him in defining faith as belief based on authority have held that the contents of revelation are appropriate matters for faith and that the truths accessible only by revelation and not also by strict natural theology are strictly matters of faith and cannot be objects of theoretical knowledge or understanding. They have held, however, that natural theology can provide us with theoretical knowledge or understanding of some matters that can be held by faith. When we acquire a rational proof for a proposition previously held on testimony or come to see the theoretical explanation of it, our faith (with respect to that proposition) is thereby replaced with or converted to knowledge or understanding. Hence, to the extent that natural theology is successful we will have knowledge or understanding, but in so far as we must rely on revelation and testimony for truths about God we will have only faith (see Faith §4).

If we adopt a broader conception of natural theology, however, we lose the basis for a clear distinction between faith and knowledge or understanding. This is because, unlike demonstrative science, some forms of dialectical inquiry can make use of arguments that appeal to legitimate authority. Augustine points out that virtually everything we believe about the past, other parts of the world, and other people's thoughts and attitudes is based on someone's testimony. Since we typically suppose that we have good reasons for believing things of this sort (because we typically suppose we have good reason to accept the testimony on which those beliefs are based), it follows that propositions whose epistemic grounding essentially involves testimony may not be in principle inaccessible to the natural theologian who uses dialectic. Broad natural theologians might find themselves in a position to establish, solely on the basis of our natural cognitive resources (broadly construed), the legitimate authority of some body of revelation (for example, the historical reliability of the biblical accounts of extraordinary manifestations of divine activity). In that case, the truth of any proposition contained in that body of revelation, including those that must remain for the strict natural theologian strictly matters of faith, might be accessible to the broad natural theologian.

It might turn out, then, that with respect to their contents, there is no distinction between broad natural theology and revelation-based theology. That is to say, it might be that there is no territory open to the practitioner of revelation-based theology that is not in principle also open to the practitioner of broad natural theology. Even so, we might still distinguish between the two enterprises on epistemological grounds. Practitioners of broad natural

theology will accept a proposition only in so far as they take it to be an acceptable datum for natural theology or grounded by a suitable argument in it. By contrast, practitioners of revelation-based theology can accept a proposition simply because they believe it to be revealed, regardless of whether that belief or the proposition itself is adequately grounded for them.

4 Critiques of natural theology

Most philosophical attacks on natural theology are directed at particular arguments in natural theology - at one or another of the proofs for God's existence, for example. Objections to Anselm's ontological argument date back to Anselm's contemporary, the eleventh-century monk Gaunilo (see Anselm of Canterbury §4). René Descartes' proofs for God's existence found a contemporary critic in Thomas Hobbes (§3) (see Descartes, R. §6). David Hume (§6) offered a sustained critique of the argument from design popular among Enlightenment thinkers and developed his empiricist principles into an attack on the possibility of miracles and the evidential value of appeals to their alleged occurrence. The Humean project has been elaborated and extended in the twentieth century by the influential work of J.L. Mackie (1982).

Other critics have objected not only to the particular arguments of natural theology but also to the enterprise itself. Immanuel Kant (§8) argued that human knowledge is attainable only within the realm of possible human experience, and he concluded that since God is an object outside that realm, human knowledge cannot extend to divine matters. Hence, in so far as natural theology aims at attaining knowledge of the divine, it must fail. This rejection of natural theology, however, might be taken as relevant only to a certain kind of strict natural theology. In fact if Kant's own 'practical' arguments for the existence of God and the immortality of the soul can be understood as providing some epistemic justification for their conclusions (though not justification sufficient to give us knowledge strictly speaking), then they might be understood as arguments in dialectical (or broad) natural theology.

Some twentieth-century philosophers, following contemporary accounts of the nature of language, have developed analyses of religious discourse that undermine natural theology. Developing one strain of empiricism, A.J. Ayer (§2) and R.B. Braithwaite, for example, have defended non-cognitivist views of religious language. According to Ayer (1946), to say that God exists is to make a metaphysical utterance that is empirically unverifiable and so neither true nor false. Religious discourse, in so far as it purports to describe a transcendent reality, is therefore literally meaningless. Working in the same tradition, Braithwaite (1955) has argued that although religious beliefs are neither true nor false, they are expressive of a practical commitment to a certain religious way of life. On views of this sort, there are no propositions about God for natural theology to establish (see Religious language §3).

Following Wittgensteinian insights into the nature of language, philosophers such as Norman Malcolm (1977) have argued that religious discourse constitutes a particular language game. As with any language game, there can be no question about the truth, justifiability or legitimacy of the game itself. Questions about the truth or falsity of the beliefs that constitute a language game can be asked only from within the game itself. On this view, a natural theology that aims at providing ultimate grounding for religious beliefs is fundamentally misconceived.

Some critics have had religious grounds for scepticism about the very enterprise of natural theology. Søren Kierkegaard (§§4-5), for example, claimed that objective reflection on the truth of divine matters of the sort that is essential to natural theology necessarily fails to attain religious truth. According to Kierkegaard, the highest truth attainable by an existing individual is an infinite subjective passion that is itself paradoxical from the objective point of view. Natural theology will be not just useless but inimical to the attainment of religious truth. Developing both Kantian and Kierkegaardian objections, theologians such as Karl Barth (§§2-4) have claimed that the Christian God is wholly other and, as such, knowable only in virtue of God's own self-revelation. Barth (1960) concluded that any enterprise that relies solely on natural human resources cannot arrive at knowledge of God.

5 Natural atheology and apologetics

Natural theology is typically thought of as aiming at a positive result - that is, at proving that God exists, establishing that theism is true, or justifying religious belief in general or particular religious beliefs. Arguments in natural theology that are unsuccessful fail to achieve these positive results. But the truth about God (or divine matters generally) might be negative, that is, it might be that there is no God, that theism is false and so forth. So

we might think of arguments that have these negative results as also being part of natural theology. Alternatively, we might think of them as part of a distinct enterprise, natural *atheology*, that aims at establishing the falsity of theism or of certain sorts of religious belief.

Natural atheology has had two prominent strands. One strand argues that the concept of God is in some way incoherent or internally inconsistent. Some philosophers have supposed that the concepts of certain attributes commonly thought to be essential to God are incoherent, and that therefore no being possessing such attributes can exist. The well-known paradoxes of omnipotence - for example, that an omnipotent being must be able to create a stone too big for an omnipotent being to lift - purport to show that no being could be omnipotent (see Omnipotence §2). Others have maintained that certain of the divine attributes are incompatible with one another. It has been argued, for example, that no being could be both omniscient and immutable, since an omniscient being's knowledge must be constantly changing as facts about the world change (see Immutability §3).

The other main strand of natural atheology argues that the existence of God or the truth of some set of religious beliefs is incompatible with things we know about the world. By far the most famous atheological argument, the argument from evil, attempts to show that the existence of an omnipotent, omniscient, perfectly good God is incompatible with the existence of evil, or that the kinds and amount of evil we find in our world in some way make improbable the existence of the theistic God or render the theistic hypothesis less probable than some rival hypothesis (see Evil, problem of).

Defending theism against atheological attack has been the traditional role of apologetics. Defence might consist merely in showing that atheological arguments do not succeed in establishing their negative conclusions, or it might involve the more ambitious project of showing how the difficulties alleged against theism can be accommodated and explained by theism. The latter, more ambitious sort of defence against the argument from evil is theodicy - the attempt to justify God's goodness by identifying the morally sufficient reason that justifies God in causing or permitting the evil that in fact exists. Apologetics generally and theodicy in particular can be thought of as parts of natural theology.

6 Clarificatory and philosophical theology

Natural theology, whether strictly or broadly conceived, is justificatory in nature; that is, it is concerned with establishing the truth of certain theological propositions using standard techniques of reasoning starting from propositions that have some appropriate degree of epistemic justification. Many sorts of philosophical reflection, however, are primarily clarificatory rather than justificatory in nature. Philosophical reflection on and explication of the nature and content of a particular theory typically involves the analysis of the concepts central to that theory, the examination of the theory's coherence and internal consistency, and the assessment of the theory's relations to other theories and beliefs. These kinds of analytic and systematic tasks can be and often are carried out apart from questions about the theory's truth or our justification in accepting it; indeed the successful completion of some of these clarificatory tasks is in some ways a prerequisite for assessing the truth of a theory. We can therefore identify an enterprise whose aim is the philosophical clarification and explication of theories about divine matters or the particular beliefs that comprise such theories. We might call this enterprise *clarificatory* theology.

Clarificatory theology is like natural theology with respect to its methods: it uses standard techniques of reasoning (where those include tasks such as definition and conceptual analysis as well as techniques for constructing and evaluating arguments). But it is unlike natural theology in placing no epistemic restrictions on the sorts of propositions or theories that it can take as its starting points. Clarificatory theology might, for example, take the Christian notion of atonement as a datum and engage in philosophical clarification and explication of that notion without requiring that we justifiably believe or know that God exists, that an atonement has in fact occurred or anything of the sort.

If we think of the justification and clarification of religious beliefs and theories as two ways in which our natural cognitive resources can be brought to bear on divine matters, then we can take natural theology and clarificatory theology to be species of a single genus that we might call *philosophical* theology. Philosophical theology is the enterprise that attempts to understand divine matters using the techniques and methods of human reason, particularly as those have been developed within philosophy.

Naturalism in ethics

Ethical naturalism is the project of fitting an account of ethics into a naturalistic worldview. It includes nihilistic theories, which see no place for real values and no successful role for ethical thought in a purely natural world. The term 'naturalism' is often used more narrowly, however, to refer to cognitivist naturalism, which holds that ethical facts are simply natural facts and that ethical thought succeeds in discovering them.

G.E. Moore (1903), attacked cognitivist naturalism as mistaken in principle, for committing what he called the 'naturalistic fallacy'. He thought a simple test showed that ethical facts could not be natural facts (the 'fallacy' lay in believing they could be), and he took it to follow that ethical knowledge would have to rest on nonsensory intuition. Later writers have added other arguments for the same conclusions. Moore himself was in no sense a naturalist, since he thought that ethics could be given a 'non-natural' basis. Many who elaborated his criticisms of cognitivist naturalism, however, have done so on behalf of generic ethical naturalism, and so have defended either ethical nihilism or else some more modest constructive position, usually a version of noncognitivism. Noncognitivists concede to nihilists that nature contains no real values, but deny that it was ever the function of ethical thought to discover such things. They thus leave ethical thought room for success at some other task, such as providing the agent with direction for action.

Defenders of cognitivist naturalism deny that there is a 'naturalistic fallacy' or that ethical knowledge need rest on intuition; and they have accused Moore and his successors of relying on dubious assumptions in metaphysics, epistemology, the philosophy of language and the philosophy of mind. Thus many difficult philosophical issues have been implicated in the debate.

1 Naturalism versus other issues

The focus in contemporary debates about ethical naturalism is on the relation of ethics to a naturalistic worldview, one that takes the emerging scientific picture of the world as approximately accurate and that rejects belief in the supernatural. Ethical nihilists deny that real values can fit into such a picture. Cognitivist naturalists reply that they can, and that we can learn about them by methods similar to those by which we learn of other natural facts. Noncognitivists disagree with cognitivists on both counts; they distinguish themselves from nihilists, however, by insisting that the primary function of ethical thought is not to discover ethical truths but rather to direct action, a task at which it may succeed (see Analytic ethics; Moral realism).

These debates need to be distinguished from others with which they are sometimes confused. The ancient Sophists initiated a discussion, for example, about whether morality exists by nature or by convention (see Sophists; Nature and convention). Although answers to this somewhat ill-defined question may bear on contemporary issues about ethical naturalism, the relation is not simple. That morality requires 'following nature' is sometimes a version of cognitivist naturalism, but sometimes not (as when 'following nature' is explained in theological terms). Many versions of cognitivist naturalism take no stand on this thesis, moreover, and others, such as versions of social relativism, appear to come down on the 'convention' side of the older debate (see Social relativism).

Questions about naturalism should also be distinguished from more general issues about 'facts and values' (see Fact/value distinction). One question is whether there are ethical facts. Cognitivist naturalists answer yes, but so did Moore and so do theological moralists. Noncognitivists such as R.M. Hare (1952), to be sure, reject cognitivist naturalism because they think values could not be facts of any sort, even if there were (or are) supernatural facts; and in this they can claim inspiration from Moore (1903), who introduced his peculiar category of the 'non-natural' to accommodate ethical facts precisely because he thought such facts could be neither natural nor 'metaphysical' (his term for the supernatural) (see Moore, G.E. §1). But others who applaud Moore's arguments against cognitivist naturalism, such as J.L. Mackie (1977), think there would be no bar to taking certain supernatural facts (for example, about Plato's forms), if there were such facts, to be ethical facts.

So there seems no thesis about whether there are, or could be, ethical facts, which uniquely distinguishes either generic ethical naturalists, cognitivist naturalists or their critics. Another question is whether, from premises entirely about nonethical facts, there are reasonable inferences to any ethical conclusions (see Logic of ethical discourse §§2-4). Here all critics of cognitivist naturalism answer no. (The doctrine they thereby affirm is called

the autonomy of ethics.) Many writers, again beginning with Moore, and including some defenders of cognitivist naturalism, have thought the latter doctrine committed to answering yes. Indeed, in the third quarter of the twentieth century, this question was often understood to be the central issue between cognitivist naturalists and their critics. For reasons which shall be noted, however, many cognitivist naturalists after that time have seen no need to deny the autonomy of ethics. Thus, on this issue, there is agreement among critics of cognitivist naturalism but none among its defenders.

2 Vindicating and debunking

We have distinguished ethical naturalism in the generic sense from significant subcategories: nihilist, cognitivist, noncognitivist. Within these latter two categories we can note one other important distinction. All versions of cognitivist naturalism will allow for discovering that some ethical statements are true, but they may nevertheless differ greatly on how important a ‘success’ they thereby make possible for ethical thought. For some of these views - for example, the suggestion that judgments of right and wrong merely report local social conventions - seem intended to represent ethical considerations as far less important and less worthy of respect than they have seemed; whereas others, such as ideal contractarian or Aristotelian views, seem designed not to debunk but instead to vindicate the practical importance conventionally ascribed to ethics. Positions at the debunking end of this scale thus join with nihilism in deflating the importance of ethical thought, though on the basis of a thesis about what makes ethical beliefs true rather than on the grounds that they are never true.

A similar distinction can be drawn within noncognitivism. Any noncognitivist theory will specify some role, such as guiding conduct, at which ethical discourse may succeed. But early versions, such as A.J. Ayer’s (1936), did not suggest that this would be success at anything rational or likely to command respect (see Emotivism). Later versions, however, such as those of Simon Blackburn (1993) or Allan Gibbard (1990), disown carefully any intention of representing ethical thought as defective or ‘second-rate’. Crucial to their case is the claim that, even on a noncognitivist understanding, ethical thought can systematically mimic most of the features - such as answerability to evidence and to requirements of consistency - that make it appear to aim at discovering ethical truths. This defence suggests a way, however, in which even the most vindicatory version of noncognitivism is likely to seem at a disadvantage when compared with a comparably motivated cognitivist naturalism, if the latter is truly available. For why settle for mimicry if one could have the real thing? The answer, according to these noncognitivists, is that the real thing is not available; and their reasons are mostly familiar from the tradition noted above, of thinking cognitivist naturalism vulnerable to objections of principle. So we need to turn to those objections.

3 Metaphysics

These arguments may for convenience be divided into the metaphysical and the epistemological, although the best-known of them, the ‘open question’ argument, through which Moore tried to expose the fallacy in all ‘naturalistic ethics’, draws a metaphysical conclusion from partly epistemic premises. Moore assumed, in what is arguably already an oversimplification, that any version of cognitivist naturalism would rest on a reductive property-identification such as ‘goodness = pleasure’. Further, he thought (1) that any such identification could be true only if the expressions flanking the identity-sign are synonyms for a speaker who understands them both, and (2) that the terms could be shown not to be synonyms by the mere fact that such a speaker could conceivably doubt the identity-statement: by the fact, in other words, that it remains in this minimal sense an ‘open question’ whether the identification is correct. Thus, from the mere fact that doubt about this sample doctrine is conceivable, Moore took it to follow that it is false. Even on these assumptions, it is unclear why he was confident that every version of cognitivist naturalism would fail his test; but his assumptions have in any case met severe criticism. Assumption (2) has been attacked as too stringent a test for synonymy, assumption (1) questioned on the deeper ground that synonymy seems in any case not required for the truth of identifications of this form, as illustrated by such significant discoveries as that water is H_2O or that heat is molecular motion.

Critics of cognitivist naturalism have asked in reply how good a model these scientific identifications could provide for any proposed in ethics. Certainly, there could be little resemblance if Gilbert Harman (1977) were right that ethical notions never seem useful in explaining any natural facts or events. For these scientific identifications are accepted partly because of an approximate match between, for example, the effects common sense explains by

reference to heat and the ones attributed to molecular motion. But cognitivist naturalists have replied to Harman that the explanatory use of ethical notions is endemic to ordinary thought. Social justice has long been conceived as a condition that, without undue deception or coercion, will stabilize a society and permit it to flourish; moral decency is taken to be a trait that keeps some people from doing things that come easily to others.

Another cluster of objections concerns the reason-giving and motivating roles of moral facts. Some critics deny that natural facts could possess the rational authority for action expected of ethical facts. Others, especially noncognitivists, deny that natural facts could motivate as ethical facts would have to do when recognized (see Moral motivation). To both challenges cognitivist naturalists typically offer a two-part response. First, any vindicatory version will attempt to show about at least some ethical values why, on a full understanding, they would command a strong allegiance from most reflective agents. Anyone who knows or assumes that such an account is available would tend to be motivated by ethical considerations, moreover.

Second, even naturalists who hope to vindicate much of ethics in this way will oppose attempts to dismiss debunking accounts prematurely and for the wrong reason. Conventional thought may accord ethical considerations rational authority, but as with many conventional beliefs about ethics it remains to be seen how well this assumption will withstand critical challenge. Plato has Thrasymachus in the *Republic* say that justice is nothing but the interest of the ruler; on a plausible reading, Karl Marx holds (to oversimplify considerably) that it is nothing but the interest of a ruling class (see Wood 1981). These are both on their face naturalistic but deliberately debunking accounts. It strikes cognitivist naturalists as too easy a victory over such disturbing suggestions to hold that they can be rejected a priori simply because they threaten the conventional assumption that justice merits respect. Critics sometimes maintain that at least the most general ethical categories (the good, the right) must be immune from such debunking challenges, but cognitivist naturalists argue that the history of ethical debate suggests otherwise. If they are right, then they can point to agents, those advancing the debunking positions, who are recognized as joining issue with more conventional views, but for whom these ethical considerations are not motivating.

4 Epistemology

Moore thought that ethical knowledge would have to rest on ethical intuition, a source unlikely to be welcomed by an ethical naturalist (see Intuitionism in ethics). But there is a simple argument for Moore's view from two premises that have been widely accepted by philosophers. One is that ethics is autonomous, that there is no reasonable inference to any ethical conclusion from entirely nonethical premises (see Autonomy, ethical §5). The other is a traditional and very influential doctrine about knowledge called foundationalism (see Foundationalism). According to foundationalism, everything we know to be true must either be based on a reasonable inference from other things we know, or else must be known directly, without inference; and all knowledge of the first sort must ultimately rest entirely on a foundation provided by the other, noninferential kind. Together these doctrines entail that if we have any ethical knowledge at all, some of it must be noninferential (or, in equivalent traditional terminology, intuitive). For if we have any ethical knowledge by inference, that knowledge must (by foundationalism) be obtainable by a reasonable inference from things we know without inference; and (by the autonomy of ethics) the premises of that inference must be partly ethical.

For much of the twentieth century, most cognitivist naturalists, when faced with this argument, agreed with their critics that they would have to deny the autonomy of ethics. But that doctrine has continued to seem more plausible than the arguments often proposed in its defence. Prominent defences of it have appealed to the controversial theses already mentioned, deriving it, for example, from the principle (itself not obvious) that action-guiding conclusions cannot be inferred from premises that severally lack this property. The resilience of the doctrine is arguably due less to such defences than to its being an instance of what has come to be recognized as a more general phenomenon: that when evidence from one area is brought to bear on a second, it typically has to be applied in light of assumptions one already has about the second area. Thus, to take an important example, it was a fond hope of empiricist philosophy of science to display standard scientific reasoning as proceeding from a foundation of empirical observation, guided only by methodological principles that are entirely neutral on scientific issues; but there has come to be near-consensus that this cannot be done. Scientific reasoning instead adjusts information about empirical evidence along with a diverse body of theory already tentatively in place, in the direction of a better overall fit. The process is quite similar to what John Rawls (1971) has called the search for

a ‘reflective equilibrium’ among our views at different levels of generality, although Rawls described the procedure only for ethics (see Moral justification §2).

One moral drawn from these considerations by many philosophers is that foundationalism is mistaken. Although there is controversy over what account of knowledge to substitute, moreover, the reasonable alternatives have in common that, even when conjoined with the autonomy of ethics, they do not require that ethical knowledge rest on intuition. One suggestion, for example, is that scientific reasoning can lead to knowledge because the process of progressive readjustment described above is generally reliable, in that it tends over time to eliminate error and bring the body of scientific beliefs closer to the truth; and that scientific reasoning has had this feature partly because enough of the theoretical beliefs from which it begins have been at least approximately true. Some cognitivist naturalists have defended a similar thesis about ethical reasoning; and their position no more requires noninferential knowledge of goods or duties than the comparable thesis about science requires intuitions of quarks or electrons.

Each of these objections to cognitivist naturalism can be further elaborated, as can the replies. If a fallacy is a mistake easily agreed upon once it is pointed out, there is no naturalistic fallacy. There remains, however, a complex debate about whether any form of cognitivist naturalism can prove satisfactory, a debate that quickly takes one into all the major areas of philosophy.

Gibbard, A. (1990) *Wise Choices, Apt Feelings*, Cambridge, MA: Harvard University Press.(Perhaps the most carefully worked out version of noncognitivism, which extends that doctrine beyond ethics to cover judgments of rationality; a sympathy for ‘Moore-like’ dismissals of cognitivist naturalism is conjoined with the reflection that the author’s disagreement with that position may in the end be empirical. Pages 150-250 explore the extent to which, on the account presented, normative judgment ‘mimics the search for truth’ (218).)

Hare, R.M. (1952) *The Language of Morals*, Oxford: Clarendon Press.(A highly influential presentation of noncognitivism, which attempts to derive the autonomy of ethics from the distinctively action-guiding character of ethical language. Like most writers influenced by Moore, Hare uses the term ‘naturalism’ for what this entry calls cognitivist naturalism.)

Harman, G. (1977) *The Nature of Morality*, New York: Oxford University Press, chaps 1-2.(Presents the argument that supposed moral facts seem irrelevant to naturalistic explanation, without committing himself to this conclusion.)

Mackie, J.L. (1977) *Ethics: Inventing Right and Wrong*, Harmondsworth: Penguin, ch. 1.(Makes a vigorous naturalistic argument for ethical nihilism.)

Moore, G.E. (1903) *Principia Ethica*, Cambridge: Cambridge University Press, sections 1-17.(Dense, technical and, by Moore’s later admission, sometimes confused, this passage presents the ‘open question’ argument and claims to refute cognitivist naturalism, called by Moore ‘naturalistic ethics’.)

Plato (*c*.380-367 BC) *Republic*, trans. G. Grube, revised by C. Reeve, Indianapolis, IN: Hackett Publishing Company, 1992, book I.(Presents a classic debate about the nature and value of justice.)

Railton, P. (1992) ‘Some Questions about the Justification of Morality’, in J.E. Tomberlin (ed.) *Ethics, Philosophical Perspectives* 6, Atascadero, CA: Ridgeview Publishing Co., 27-53.(A subtle discussion of how

vindicatory a naturalistic theory of ethics can be, and should be required to be.)

Rawls, J. (1971) *A Theory of Justice*, Cambridge, MA: Belknap Press, ch. 1, section 9.(Describes the process of seeking a ‘reflective equilibrium’ among one’s ethical and other beliefs. This is accepted as an approximately accurate account of thoughtful reasoning in ethics by many who then disagree about the philosophical implications.)

Sturgeon, N.L. (1985) ‘Moral Explanations’, in D. Copp and D. Zimmerman (eds) *Reason, Truth and Morality*, Totowa, NJ: Rowman and Allenheld, 49-78.(A defence of ethical naturalism, with special reference to the explanatory relevance of ethical facts.)

Wood, A.W. (1981) *Karl Marx*, London: Routledge & Kegan Paul, chaps 9, 10.(Defends a careful version of an interpretation according to which Marx holds (to put it much less carefully) that justice is nothing but the interest of a ruling class.)

Naturalism in social science

Naturalism is a term used in several ways. The more specific meanings of 'naturalism' in the philosophy of social sciences rest on the great popular authority acquired by modern scientific methods and forms of explanation in the wake of the seventeenth-century scientific revolution. For many of the thinkers of the European Enlightenment and their nineteenth-century followers the success of science in uncovering the laws governing the natural world was used as an argument for the extension of its methods into the study of morality, society, government and human mental life. Not only would this bring the benefit of consensus in these contested areas, but also it would provide a sound basis for ameliorative social reform. Among the most influential advocates of naturalism, in this sense, was the early nineteenth-century French philosopher Auguste Comte.

The authority of the new mechanical science, even as an account of non-human nature, continued to be resisted by romantic philosophers. However, the more limited task of resisting the scientific 'invasion' of human self-understanding was taken up by the Neo-Kantian philosophers of the latter part of the nineteenth century, in Germany. Followers and associates of this tradition (such as Windelband, Rickert, Dilthey and others) insist that there is a radical gulf between scientific knowledge of nature, and the forms of understanding which are possible in the sphere of humanly created meanings and cultures. This view is argued for in several different ways. Sometimes a contrast is made between the regularities captured in laws of nature, on the one hand, and social rules, on the other. Sometimes human consciousness and self-understanding is opposed to the non-conscious 'behaviour' of non-human beings and objects, so that studying society is more like reading a book or having a conversation than it is like studying a chemical reaction.

1 Varieties of naturalism

A 'naturalistic' approach to the social sciences may express a view about the nature and limits of our knowledge of the different subject matters, or about the appropriateness of certain methods of inquiry, or about the essential sameness of the subject matters of natural and social sciences. So, we may usefully distinguish epistemological naturalism, methodological naturalism and ontological naturalism. Also, in the case of ontological naturalism, it is important to distinguish between, on the one hand, 'reductionist' versions, and, on the other, 'non-reductionist' versions, such as 'emergent powers' or 'dialectical' naturalisms.

In most of the literature of the philosophy of social science, naturalism is taken to be primarily an epistemological doctrine, and, frequently, to be more or less identical with 'positivism' (see Positivism in the social sciences §1). Epistemological naturalism is the thesis that the social life of humans is knowable in just the same sense, and will take the same form, as knowledge of the natural world. So, the natural sciences - physics, chemistry and biology - are taken as paradigmatic for social scientific knowledge. Historically, the most influential accounts of the natural sciences have been empiricist ones, according to which scientific knowledge is characterized by its openness to empirical testing (generally by the use of experimental method), the law-like character of its general statements, the symmetry of explanation and prediction, and the clear distinction between value-judgements and factual statements. The nineteenth-century French sociologist, Auguste Comte is generally credited as the founding figure of a positivist movement, devoted to extending scientific knowledge, on this model, to the spheres of psychology and human social life. The positivists and their latter-day followers have also been committed to a view of the social sciences as technically applicable knowledge, in much the same way as knowledge in the physical sciences has enabled a degree of control and regulation of natural phenomena.

Critics of positivism have most commonly been adherents of epistemological or ontological anti-naturalism. However, the proliferation of non-empiricist accounts of the natural sciences, especially, in the Anglophone world, since the work of Thomas S. Kuhn (see Kuhn, T.S.) has opened up the possibility of versions of epistemological naturalism that reject positivism. 'Conventionalist' accounts of empirical testing serve to undermine the fact/value distinction as a distinguishing mark of science, while, various realist approaches to the nature of the natural sciences put the emphasis on the role of analogy and metaphor in the discovery of mind-independent causal mechanisms and structures in nature.

These non-empiricist accounts of natural scientific knowledge open up a complex range of possible forms that might be taken by the social sciences within the general terms of non-empiricist epistemological naturalism. The

work of Rom Harré and his associates in the field of social psychology, and of Roy Bhaskar in developing a 'critical realist' reconstruction of historical materialism are two notable developments along these lines (see Critical realism).

2 Methodological naturalism

Methodological naturalism may be defined as the commitment to applying natural science methodology for purposes of developing the social sciences. Again, methodological naturalism is most commonly associated with the positivist tradition. The central priority for such an approach is to render social processes and relations measurable and so mathematically analysable. It is widely accepted that the direct use of experimental methods is rarely possible in the social sciences - either for ethical or legal reasons, or because of the impossibility of controlling extraneous variables. So, methodological naturalists tend to opt for two main substitutes. One of these, typical of historical sociology, is the comparative method. Societies that differ in only a small number of significant features are compared with respect to some historical outcome (for example, the emergence of dictatorships or democracy) whose causes are sought. Alternatively, analysis may be carried out on large-scale data-sets to discover statistical associations (for example, between social class and morbidity or mortality) which may allow of causal inferences. Many of these techniques are common to both social and (some) natural sciences (such as epidemiology and population biology). Émile Durkheim's *Suicide* (1897) is a classic text for methodological naturalism in sociology (see Durkheim, É. §3).

Opponents of methodological naturalism commonly argue that the relation, in the social sciences, between researcher and subject matter is quite different from that which obtains in the natural sciences. Participants in human social life do so on the basis of their own understandings of what they are doing. The forms of understanding developed by social scientists are, therefore, secondary, 'understandings of understandings'. Social scientific understanding, on this view, is more like textual interpretation or, perhaps, dialogue, than it is like the external relation between the natural scientists and the physical structures and processes they study. The hermeneutic tradition that flourished in Germany in the late nineteenth century, and which returned to the philosophy of Immanuel Kant for ways to resist positivist 'invasion' of the humanities, has been the most powerful source of opposition to methodological naturalism. The British philosopher, Peter Winch, in his influential *The Idea of a Social Science* (1958), deployed his reading of the later work of Wittgenstein to reach very similar conclusions. The subsequent 'linguistic turn' in the social sciences, and the associated introduction of literary modes of social analysis under the banner of 'postmodernism' have served to put the proponents of methodological naturalism very much on the defensive.

Again, however, it may be argued that an identification of 'methodological naturalism' with comparative method and statistical analysis as experiment substitutes, relies on a narrow and distorted view of the range of methods of investigation used by natural scientists themselves. There are, for example, many parallels between the fieldwork methods of animal ethologists and the 'qualitative' research of social scientific ethnographers.

3 Ontological naturalism

However, the more fundamental objections to both epistemological and methodological naturalism tend to turn on matters of ontology. For anti-naturalists, humans, their symbolic creations, their social relations and institutional forms, are radically different in kind from the order of nature. In their different forms, anti-naturalisms may emphasize free choice and spontaneity (ruling out deterministic laws and scientific prediction), self-definition (cognitive authority of participants, not observers), rule-following (as against causal determination), or the creation of meaning (requiring interpretation, as distinct from explanation) as the key ontological feature that defeats the naturalist project. Sometimes the case for human-social ontological uniqueness is made by way of a dualistic opposition between physical mechanisms or processes, and those of the human social world, or, alternatively, some version of human/animal dualism may be relied upon.

The case for a dualistic opposition between humans and animals (what has come to be called, by its opponents, 'human exemptionalism') may rest on a range of supposedly unique features of human individuals, or of the species as a whole. The attributes of self-consciousness, language-use, and moral agency are most commonly emphasized, but especially in traditions of thought influenced by Marx and Hegel, such distinctive properties of human groups as social production (rather than mere collection), tool-use, and historicity may be emphasized.

Against this, ontological naturalists have available two broad strategies. One is to focus on those aspects of their lives which humans have in common with (other) animal species. The other is to rely on modern research in the life sciences that seems increasingly to have ‘closed the gap’ in just those areas of human ‘uniqueness’ which the anti-naturalists prize. The Darwinian revolution established the phylogenetic kinship between humans and other animal species, and set the scene for later approaches to the study of animal behaviour in the field, and of the ecology of the human species itself. Tool-use and the learning of elements of human sign-language among chimps, as well as widespread evidence of high levels of social cooperation, emotional complexity and a rich psychic life in other animal species are now difficult to deny.

Proponents of naturalism sometimes accuse anti-naturalists of an arrogant ‘species-chauvinism’, and point to the inability of ‘human-exemptionalist’ explanatory strategies to deal with the material dimensions of human ecological destruction. Advocates of ontological naturalism also point out how the reduction of human social life to ‘text’, which is implicit in the ‘linguistic turn’, obscures or renders marginal the material dimensions of human deprivation, oppression, and unnecessary suffering that has been at the heart of much critical social science.

But the anti-naturalists can, with some force, point out that, in its various forms, ontological naturalism in the social sciences has itself served oppressive interests. The Malthusian ‘law of population’, social Darwinism, Nazi racial science, and, in our own day, sociobiology have all been used as means of oppression. Naturalisms of various kinds have also been widely used to represent as ‘natural’ and therefore unalterable all manner of unjust and exploitative institutions.

4 Non-reductionist naturalisms

It may be that no single solution may be found to the dilemmas and tensions posed by this confrontation between naturalisms and their opponents. It is certain that there are no easy or simple ways forward. However, from the side of ontological naturalism a number of intellectual strategies are available which show some promise of answering the main objections made by anti-naturalists. It is quite possible, for example, within a broadly naturalistic framework, to acknowledge the specificity of the human species without denying our kinship with other species. Indeed, human powers of symbolic communication, autonomous agency and capacity for history can themselves be seen not as *sui generis*, but as consequences of our biological peculiarities - ‘premature’ birth, prolonged infantile dependency, bipedalism, highly developed central nervous system, and so on.

The social world humans create as their ‘second nature’ may also be understood as irreducibly heterogeneous in its make-up - some of it is, literally, text, while much more of it is text-like. Humans live all their social relations through some form of symbolic understanding, so that a hermeneutic aspect, or moment, is necessary to all social science. However, to suppose that human social life is composed wholly of understandings, as if there were nothing beyond discourse which these ‘understandings’ are understandings (or misunderstandings) of, would be to commit a linguistic reduction as difficult to defend as its polar opposite naturalistic reductionism.

For an advocate of naturalism to go this far in the direction of the anti-naturalist case would require a complex and open-textured ontology, incompatible with the forms of reductionist naturalism widely criticized by the linguistic and hermeneutic traditions. In other words, to be defensible against the main anti-naturalist critique, naturalism would need to avoid the ‘reductionist’ project of representing the subject matter of the social sciences as the direct or unmediated effect of the operation of laws and mechanisms proper to the natural sciences.

A non-reductionist naturalism, making use of the ideas of a hierarchy of more or less autonomous levels of organization of matter, each with its own, qualitatively new, ‘emergent’ powers or properties has been one fruitful way of sustaining the main insights of a naturalistic approach, without falling foul of what is valid in the anti-naturalistic critique.

Such hierarchical, ‘emergent powers’ ontologies enable their advocates to recognize in the various subject matters of the different natural and social sciences, more or less discrete and autonomous object-domains, while at the same time making no concessions to spiritualistic, vitalist, or supernatural beliefs. ‘Emergent powers’, or ‘dialectical’ naturalisms remain committed to the doctrines that the beings making up the object-domains of the various sciences are all ultimately composed of the same basic ‘stuff’, and that at whatever level of organization they exist, they behave consistently with the laws governing the lower levels of organization.

On this view, social (economic, political, and so on) structures and practices are held to exist independently of our (social scientific) knowledge of them, and as objects of study in their own right, with their own distinctive sets of properties, powers, tendencies, and so on. Nevertheless, and this is the hallmark of a naturalistic approach, these structures and practices, with their distinctive properties, powers and tendencies exist only in virtue of their status as more or less enduring forms of organization of the lower-level entities (people, buildings, tools, animals and plants), and so on down the hierarchy of organization.

Clearly, ideas such as 'emergent powers' enable people who want to work within a naturalistic framework to take account of the very powerful arguments used by anti-naturalists against reducive forms of naturalism (such as sociobiology and Malthusianism). To some extent this may lead to a convergence of views between non-reductive naturalisms and the less extreme forms of anti-naturalism. However, in research-practice in the social sciences, this difference of view tends to take the shape of a division of labour between different topics and sub-disciplines. So, for example, cultural anthropology and sociology of culture have tended to be dominated by anti-naturalistic approaches, while studies of social 'systems', power-structures, social class and stratification and so on, have more commonly been governed by epistemological and methodological, if not ontological naturalism.

Naturalized epistemology

The term 'naturalized epistemology' was coined by W.V. Quine to refer to an approach to epistemology which he introduced in his 1969 essay 'Epistemology Naturalized'. *Many of the moves that are distinctive of naturalized epistemology were made by David Hume, but Quine's essay fixes the sense of the term as it is used today.*

Naturalized epistemology has critical as well as constructive thrusts. In a critical spirit, 'naturalists' (theorists who identify with the label 'naturalized epistemology') abandon several assumptions that are part of the tradition. They reject Descartes' vision of epistemology as the attempt to convert our beliefs into an edifice resting on a foundation about which we have complete certainty. Descartes is wrong to equate knowledge with certainty, and wrong to think that knowledge is available through a priori theorizing, through reasoning which makes no use of experience. Nor should epistemology continue as David Hume's attempt to rest knowledge on an introspective study of the mind's contents. Moreover, the global sceptic's claim that there is no way to justify all our views at once, should either be conceded or ignored.

On the constructive side, naturalists suggest that in investigating knowledge we rely on the apparatus, techniques and assumptions of natural science. Accordingly, naturalized epistemology will be a scientific (and hence neither indefeasible nor a priori) explanation of how it is that some beliefs come to be knowledge. Issues of scepticism will be addressed only when they come up in the course of a scientific investigation.

Quine's seminal essay lays out the core of naturalized epistemology, but subsequent naturalists disagree on the appropriate responses to several issues, among them the following: First, may theories be tested on the basis of (independently plausible) theory-neutral observation, or are observations simply more theory? Second, after being naturalized, does epistemology survive as an autonomous discipline? Quine argues that epistemology should become a subfield of natural science, presumably a part of psychology, so that there is no separate field left specifically to philosophers. But can all our questions about knowledge be answered by natural scientists? Third, the claim that epistemology explains how knowledge comes to be suggests that epistemology will merely describe the origins of beliefs we take to be known; but what is the relationship between such descriptive issues and normative issues such as that of how we ought to arrive at our views? Fourth, to what extent is the new approach to epistemology susceptible to sceptical concerns such as those that so plagued traditional epistemologists, and how effective a response can be made to those concerns?

1 Hume's anticipation of naturalized epistemology

The naturalizing movement in epistemology is the continuation of Hume's rebellion against Descartes' view about knowledge. Like Descartes, Hume wanted to conduct an investigation of the mind and its operations, including 'the operations we perform in our reasonings'. But five features of Hume's approach place him far closer to contemporary naturalism than to Cartesianism.

First, while Descartes wished to leave no room for doubt, Hume explicitly took for granted the trustworthiness of the very faculties whose operations he wanted to investigate. Later naturalists (theorists who identify with the label 'naturalized epistemology') make a parallel move: they trust the techniques and assumptions of science even while investigating how (scientific) knowledge is possible. Hume assumed that our mental faculties are trustworthy because it would be pointless to attempt to test their accuracy; after all, any test required their use. In fact, it was *because* Hume supposed that the mental faculties generated knowledge (or at least rational belief) that he thought the clarification of their workings would shed light on the normative question of what an epistemic agent ought to believe. His project still had a critical edge, for when Hume found any belief that could not be satisfactorily accounted for in terms of standard human faculties, he recommended throwing it out as baseless.

Second, like later naturalists, Hume modelled his epistemology after the emerging natural sciences, where empirical confirmation served as the basis for claims. He thought that knowledge encompasses everything we can discover using all our mental faculties, including experience and what we can discover by applying our mental faculties to themselves.

Third, like contemporary naturalists, Hume was prepared to say that some knowledge is the product of purely causal mechanisms rather than reason (or reasoning), since through introspection Hume thought he could detect a

causal mechanism at work. The mechanism he detected itself produces knowledge of causal relations, on the basis of which we believe in matters of fact, which are facts that hold contingently and whose negations indicate real possibilities (see Hume, D. §2; Causation §1). Custom, prompted by experience, is the mechanism through which we form our suppositions concerning causal relations. Hume does not recommend doubt about the products of custom. After all, the mind is functioning in a healthy, normal way when it is under the influence of custom, and reasoning can begin only after custom does its work. We should begin to question our beliefs only when we find that they are arrived at while the mind is not functioning in the normal way science describes.

Fourth, like many contemporary naturalists, Hume explains some of the mechanisms responsible for knowledge (such as custom) in terms of survival value. The linking of causes to effects is so important to human survival that it would have been a mistake for ‘nature’ to entrust it to our reason ‘which is…extremely liable to error’. Better to entrust it to ‘some instinct or mechanical tendency, which may be infallible in its operations, may discover itself at the first appearance of life and thought, and may be independent of all the laboured deductions of the understanding’ (Hume [1748/51] 1975: 55). Years later, W.V. Quine and other naturalists will speak in the same vein. Quine (1974: 20) explains induction in terms of natural selection, and disavows any claim to have justified induction. ‘In the matter of justifying induction we are back with Hume, where we doubtless belong’.

Fifth, Hume is with contemporary naturalists in their reactions to scepticism. As he had to, since he put his trust in his faculties, Hume rejected Descartes’ idea that to know that our beliefs are true is to be in a position to place all our beliefs beyond doubt at once. Hume saw that it is not even possible to *justify* all our views at once. No more than Descartes could Hume use his faculties to assess his epistemic prospects without first assuming that they were reliable. In the last section of the *Enquiry Concerning Human Understanding* (1748/51), Hume mentions scepticism and simply acknowledges that truly global doubts would be ‘entirely incurable’.

2 Internalism versus externalism

Like Hume, contemporary naturalists are empiricists. For example, in ‘Epistemology Naturalized’ Quine explicitly affirms a version of Humean empiricism:

> It was sad for epistemologists, Hume and others, to have to acquiesce in the impossibility of strictly deriving the science of the external world from sensory evidence. Two cardinal tenets of empiricism remained unassailable, however, and so remain to this day. One is that whatever evidence there is for science is sensory evidence. The other…is that all inculcation of meanings of words must rest ultimately on sensory evidence.
>
> (Quine 1969: 75)

But contemporary naturalists do not have in mind the introspective sort of empiricism advocated by Hume but, rather, intersubjective empiricism. Instead of simply taking our mental faculties and the data of introspection for granted and accounting for knowledge from that perspective, Quine and other naturalists suggest that we take a more full-bodied version of scientific practice for granted, and account for knowledge from *that* perspective. The empiricist science on which naturalists rely is conducted in the public domain. Scientists use microscopes and other instruments to extend their senses, and the observations upon which they rely are not data of introspection but rather observations that are at least in principle publicly confirmable (see Empiricism; Introspection).

Naturalists think that the stimulation of sensory receptors helps to determine whether or not people know the truth of beliefs that are causally linked to those stimulations. Yet the stimulations themselves are usually not noticed by the people in whom they occur. Naturalists are *externalists*, defined by Laurence BonJour (1985), following D.M. Armstrong (1973), as theorists according to whom facts that are external to an agent’s conception of the situation can serve to justify that agent’s beliefs in a way that is sufficient for knowledge (see Internalism and externalism in epistemology). *Internalists*, by contrast, would insist that all knowledge is based on justifications that are in some sense in the cognitive possession of the knower. A related view is that epistemology, or knowledge about knowledge, is based on such justifications. Consider the following arguments for these internalist positions.

First, as BonJour emphasizes, justifications that are in no way possessed by an agent are completely arbitrary (unsupported), at least so far as the agent can tell from the agent’s own point of view, and accepting arbitrary beliefs is a bad idea from the standpoint of getting to the truth, which is the goal of the epistemic agent. Yet externalists claim that it is possible for agents to acquire knowledge through sources about which those agents

believe little or nothing. Their sources might be a causal chain, a reliable belief-formation process, an information channel, or all three (see Knowledge, causal theory of; Information theory and epistemology; Reliabilism). Internalists disagree, since it is epistemically irresponsible to believe something through some avenue without checking out the truth-conductivity credentials of that avenue.

The main problem with this first line of thought is that the internalists' assumptions seem to lead immediately to sceptical results. For internalists want an avenue to the truth but they want to accept nothing except what is justifiable, and nothing as justification except what is available to them 'from the inside'. That means they need an avenue to the truth that can be defended as such on the basis of what is available 'from the inside', a task that appears to be impossible. No empirical premise will serve in the defence since empirical premises will either be accepted without justification (arbitrarily) or justified on the basis of some other empirical premise, thus initiating a regress.

A second line of argument gives up on the attempt to show that all knowledge conforms to internalist assumptions, but purports to show that epistemology fits the internalist view: since logic is a priori accessible if any body of knowledge is, the thought that there is an inductive as well as a deductive logic may lead theorists to suggest that knowledge is the product of reasoning that conforms to valid deductive and inductive forms of argument. Some of the assumptions that are fed into the arguments might not conform to internalist assumptions, but the reasoning does. So we can understand epistemology to be an a priori study of the argument forms to which reasoning ought ideally to conform.

One problem here is that, unlike deductive logic, inductive logic is not the study of argument forms. Ultimately inductive logicians invoke appeals to the way the world is, appeals which internalists want to avoid. Except in trivial cases, that one statement makes another probable is a claim about the world, not about the forms of those statements. More seriously, in the phrase 'reasoning that conforms to valid argument forms' there is a conflation of argument with reasoning. As Gilbert Harman (1986) and others have emphasized, these are quite distinct things. The study of arguments and argument forms is logic; the study of reasoned belief revision is the study of the belief-management practices governing those revisions. Principles of belief management would tell us when epistemic agents should retain their beliefs and when and how they should revise them. The inference rules of logic do not tell us when revision is appropriate. Inference rules can tell us many things; for example, suppose that we believe the premises of an argument - inference rules can tell us that the premises of that argument entail its conclusion. But that is not the same thing as a recommendation that (say) we affirm the conclusion. In fact, belief-management principles might tell us that we ought to drop one of the premises rather than accept the conclusion.

Once we distinguish between logic and belief management, like Harman we may become quite sceptical about the existence of anything like an inductive logic. An inductive logic would be a logic that resembles deductive logic except that the conclusions of 'valid' inductive arguments are merely made probable by their premises, not entailed by them. That such a logic exists is not entailed by the existence of inductive reasoning, and the fact that so little progress has been made towards developing an inductive logic might lead us to suspect that there is no such subject to be investigated (see Inductive inference). Moreover, if inductive logic does not exist, good inductive reasoning cannot be simply reasoning that conforms to inductive logic. (Some have held that probability theory provides the basis of inductive logic - see Probability theory and epistemology.)

So the epistemic activity of inductive reasoning might not be illuminated by advances in 'inductive logic'. A related point is that much epistemic activity probably does not involve beliefs or any other proposition-related states at all. As Paul Churchland (1979: 128) has argued, a great deal of information is processed by infants, and their prelinguistic behaviour does not invite ascriptions of propositional attitudes to them. 'Rational… intellectual development in an infant cannot be…usefully represented by a sequence of sets of sentences suitably related'. Information processing in infants, as well as the processing by virtue of which sensory stimulations are assimilated by adult brains prior to the formation of beliefs, would presumably be articulated by principles of which epistemic agents themselves are entirely unaware and to which they could not purposely conform even if they wanted to. Churchland takes such facts to suggest that any account of knowledge in terms of 'sentences suitably related' is bound to be superficial; a proper theory would deal in more primitive parameters that apply to pre-linguistic processing, and would account for the way epistemic agents deal with beliefs as a derivative case.

In sum, critics of naturalized epistemology who say that knowledge or epistemology is based on justifications in the cognitive possession of knowers face some severe difficulties.

3 The role of observation

Naturalists disagree on many points, among them the role of observation in knowledge, the degree to which natural science is separable from epistemology, the role of normativity in epistemology, and the significance of scepticism (these latter three points are discussed in subsequent sections). One view about the role of observation in knowledge, that of Quine, is that ultimately the 'evidence for' or 'test of' our theory of the world is the prediction of the stimulations of exteroceptors. The components of our view that are most directly tested by these stimulations are observation sentences such as 'It is raining' or 'There is a rabbit'. These are directly tested by stimulations because what each *means* is a set of stimulations that prompts assent to and a set that prompts dissent from the sentence. The test of our theory of the world is therefore its ability to predict the observation sentences that verbalize our stimulations (see Quine, W.V. §2).

But many naturalists reject Quine's version of the empiricist claim that our theory rests on observation. One concern is that it is unclear how sensory stimulations can serve as *evidence* for a theory. It is relatively clear how a sentence can serve as evidence for a theory, so that we can see how observation sentences test theories, but stimulations are not sentences nor, for all we can see, any sort of propositional attitude. Moreover, the relationship between our stimulations and our assenting to observation sentences is causal, not evidential.

Another problem concerns the distinction between observation sentences (which are purported to have a special plausibility due to their intimacy with experience, so that they may serve to test theories) and the sentences in which theory is couched. Several philosophers (for example, N.R. Hanson 1968 and Paul Feyerabend 1986) have argued that there is no theory-observation distinction. There is no such thing as observation sentences whose meanings are determined by stimulations or the like. 'Observation' statements are just theoretical claims themselves, though ones we are accustomed to. So it will not do to say that our theory of the world rests on or is tested by non-theoretical observation statements. It is theory all the way down (see Observation §§3-4).

4 The autonomy of epistemology

All naturalists reject the Cartesian view that epistemology is entirely separable from and prior to other disciplines such as the sciences. But just how much autonomy epistemology retains is controversial. The most extreme view is that of Quine, who suggests that epistemology has no autonomy at all. Once we drop the idea that 'the epistemologist's goal is validation of the grounds of empirical science' we can and should, he says, 'surrender the epistemological burden to psychology'. We are to construe epistemology as the attempt to 'understand the link between observation and science', and consider ourselves 'well advised to use any available information, including that provided by the very science whose link with observation we are seeking to understand' (Quine 1969: 75-6). Hence epistemology collapses without residue into sciences such as biology and psychology. Its work is turned over to evolutionary epistemologists such as Campbell (1974) and genetic epistemologists such as Jean Piaget who attempt to explain the development of knowledge, the former explicitly in terms of the biological theory of evolution. But exactly how the sciences will distribute the work of studying knowledge is unclear. The scientific fields that study knowledge are somewhat fledgling and are not clearly differentiated. Nor is it clear how these fields are related to the sociology or sociobiology of knowledge, fields which also can be construed as part of naturalized epistemology (see Sociology of knowledge).

Some philosophers sympathetic to the naturalizing movement reject the claim that all legitimate epistemic issues can be investigated scientifically: (1) Alvin Goldman (1986) says that while epistemology and natural science are relevant to and continuous with each other, the former is not contained entirely in the latter. For example, the philosophy of logic is a branch of epistemology, but Goldman doubts that logic can be investigated scientifically. (2) Another argument is that epistemology progresses in part by studying the basic epistemic concepts, such as 'justification', 'rationality', 'warrant', 'certainty', 'knowledge' and so on. Such study is the basis for claims about what constitutes knowledge, yet philosophers, not scientists, undertake it. (3) Moreover, Goldman and many others would say, one task of epistemology is to settle normative questions such as that of how we ought to arrive at our conclusions, but science is unequipped to handle normative issues. It seems limited to telling us how we *do* arrive at our conclusions. Accordingly, epistemology might survive as an autonomous discipline in so far as it continues

to deal with deductive logic and the normative issues involved in knowledge.

Quine would reject each of these attempts to preserve an autonomous form of epistemology. To deny the first two, he would use arguments developed in 'Two Dogmas of Empiricism' (1953). (For a discussion of his approach to the third, see §5 below.) (1) That even claims of logic must face the tribunal of experience is suggested by the Quine-Duhem thesis: all statements face the 'tribunal of sense experience not individually but only as a corporate body' (Quine: 1953: 41). Hence 'no statement is immune to revision. Revision even of the logical law of the excluded middle has been proposed as a means of simplifying quantum mechanics' (Quine: 1953: 43) (see Quine, W.V. §3). (2) Progress in epistemology based on the analysis of terms is made very difficult, but is not ruled out, by Quine's holism - his claim that the meanings of particular statements and *a fortiori* terms overlap with the meanings of other statements, so that describing the meaning of a particular term requires describing its role in a complex of theory (see Atomism, ancient; Holism: mental and semantic). Moreover, analysis merely clarifies the epistemic concepts we have been employing. It does not rule out the possibility that we ought to employ different concepts, such as ones suggested by an empirical study of the brain's workings.

5 The role of normative issues

Epistemology's *descriptive* task is to identify how people actually arrive at beliefs. But what people actually do is not necessarily what they ought to do. Epistemology's *normative* task is to identify how people ought (rationally) to arrive at their beliefs, and this seems to go well beyond the descriptive task (see Normative epistemology). Not all naturalists hope that they can do away with traditional epistemology entirely and replace it with natural science. But those with this hope have trouble finding a place in their project for the normative task of epistemology, since science seems incapable of prescription. Radical naturalists could argue that the normative issue is not worth pursuing, so that reducing epistemology to its descriptive task leaves out nothing worth doing. But this is an implausible option on its face. However, their only other choice is daunting: they must argue that science can tell us how we ought to arrive at our beliefs.

Naturalists who want to argue that science can answer the normative question have two options. In the spirit of Hume they can assume that the way we arrive at our beliefs *is* (more or less) the way we ought to. (But is this assumption a scientific or an epistemological claim?) Epistemology's descriptive task is clearly within the province of science; if we completed the normative by completing the descriptive task, then science could handle both sides of traditional epistemology. Unfortunately, the claim that we ought to maintain our existing belief-management practices more or less as they are faces difficulties. The main problem lies in the data that psychologists have already gathered. These data show that normal human cognitive processes are shot through with faulty logic, bad probabilistic inferences and wishful thinking (Nisbett and Ross 1980; Taylor 1989). Beliefs with such origins do not count as knowledge.

Perhaps radical naturalists need not assume that people ought to maintain their actual belief-management practices, however. Instead, they could try arguing that discoverable facts about things other than our actual belief-management practices will allow us to accomplish epistemology's normative task (but will they be able to make these discoveries without relying on the belief-management practices they question?). For example, scientists might be able to determine that all (rational?) human beings have a common epistemic goal, whether it is reaching the truth or predicting the future course of sensory stimulation or whatever. If so, then, as Quine (1992) has pointed out, epistemology's normative task could be performed by engineers. Engineers could work out the best ways available to people (given our limited faculties and resources) for reaching their epistemic goal. We could say that these efficient methods are the ones people ought to adopt, even at the expense of fairly radical changes in their actual practices. Normative epistemology becomes part of engineering science, not a branch of epistemology that is outside of science.

But while engineers investigate efficient ways to do such things as to transport or kill people, they do not investigate the issue 'Ought we to transport or kill people?' Only after it is established that it is important to achieve some goal does engineering come into play. The issue of what epistemic agents ought to aim at is not an engineering issue. It remains a philosophical issue which cannot be absorbed into science.

The problem would be rather trivial if scientists discovered that there is a single, unvarying goal (or prioritized set of goals) which everyone wants to reach by managing their beliefs as they do, and which does not look silly on its

face. Even if the goal is ‘wired in’, we would worry about committing a ‘naturalistic fallacy’ and say ‘The fact that something is everyone’s goal does not entail that it ought to be’. Even the fact that a goal is forced on everyone does not show that we have grounds for pursuing it. Still, the temptation to take this goal as the one we ought to pursue would probably be overwhelming. However, it is by no means obvious that such a single, unvarying goal exists. In different cultures at the same time, and in the same culture at different times, people might be aiming to accomplish a variety of things by believing what they do, and the (conscious and unconscious) belief-management principles they employ might also differ widely. Given the possibility of significant diversity, epistemologists need some way to decide which competing goals and sets of belief-management principles are right for cognitive agents. Perhaps the diversity would be reduced if we focused on the goals of scientists during those times when they are being scientific. But even if it were so reduced, we would need some way of arguing that the goals of the scientists are the ones which epistemic agents ought to pursue. Several ways to handle such normative issues are open to radical naturalists.

First, they could say that belief-management principles should be evaluated from the point of view of natural selection, so that the greater the survival value of these principles, the better the principles. Once this (epistemological?) claim is made, then science can take over, by describing the belief-generating mechanisms of human beings (and other animals?) and explaining how they have the survival value they do. (But how will naturalists absorb the growing data that suggest that wishful thinking, a paradigm case of irrationality, is adaptive?)

Second, naturalists could exploit the elastic boundaries of science in order to call conceptual analysis science. Then they could use conceptual analysis to defend some view about what epistemic agents’ goals or evaluative concepts are, and make the (epistemological?) claim that belief-management principles should be evaluated from the standpoint of those goals or concepts. Supposing, as several epistemologists have, that conceptual analysis reveals truth or predictive power to be the goal of epistemic agents, then (theoretical) scientists can go on to clarify the extent to which people naturally achieve the epistemic aim. And engineering will be useful in that it might help people to find better ways to achieve the epistemic goal.

Third, Stephen Stich (1988) suggests a pragmatic approach to normative issues. First he criticizes the strategy of using conceptual analysis to discover the goals and concepts of epistemic agents. The goals and evaluative epistemic concepts that are part of ordinary language are as likely as belief-management principles themselves to vary from culture to culture (see Cognitive pluralism). So it is arbitrary to rely on them when we select management principles. ‘In the absence of any reason to think that the locally prevailing notions of epistemic evaluation are superior to the alternatives, why should we care one whit whether the cognitive processes we use are sanctioned by those evaluative concepts?’ (Stich 1988: 406). Then Stich points out that there are many common values, such as happiness or reproductive success, that are not epistemic values but can be considered relevant to our cognitive lives. Stich suggests a pragmatic approach: he makes the (epistemological? ethical?) claim that we should evaluate belief-management principles from the standpoint of these non-epistemic values. Here again theoretical science will help us to evaluate our actual belief-forming mechanisms and engineering will help us to improve upon them.

6 The significance of scepticism

Like Hume, contemporary naturalists view epistemology as the attempt to clarify how the apparatus people use in investigating the world works when used in applications for which, we assume, it is reliable, and to identify what ought and ought not count as knowledge by identifying what sorts of beliefs are endorsed by the proper use of that apparatus. Contemporaries depart from him chiefly in thinking that more must be taken for granted than the reliability of mental faculties. Recent naturalists help themselves to the whole of natural science, which can be thought of as the combination of our mental faculties with techniques and devices that extend them.

Accordingly, there is a compelling case for saying that naturalists cannot hope to put global scepticism to rest. Global scepticism says that our belief schemes (including science) are irrational because: (1) ultimately our beliefs are based on arbitrary assumptions, claims that, even upon some reflection, we cannot link to a consideration that suggests it is true; and (2) it is irrational to make arbitrary assumptions (see Scepticism §5). To argue that scientific apparatus is reliable after having simply assumed that it is would be circular, so naturalists seem committed to granting (1). Perhaps this is why naturalists rarely confront global scepticism.

Attempts, none the less, have been made. One approach involves *coherentism*, which is the claim that beliefs may derive justification by cohering one with another (see Knowledge and justification, coherence theory of). If coherentism were correct, then since it sanctions some circular justifications, naturalists could use it against (1), and argue that all our beliefs can be justified at once. Another common approach is to turn the tables on the global sceptic and point out that, like everyone else who investigates knowledge, sceptics, too, must take for granted the reliability of their investigative apparatus. As an attack on (1) this table-turning would not work. Sceptics can retort: 'Yes, all of us are in the same boat: there are assumptions we simply take for granted'. But it might well prove useful as part of an attack on (2).

It is important to notice that the global sceptic needs both (1) and (2). Once we do, we can see that even if naturalists cannot defeat (1), they can still respond to scepticism if they defeat (2). Naturalists could accept the sceptic's discovery that ultimately our views are, perforce, arbitrary, and insist that it is sometimes all right, it is sometimes rational, to believe things we simply take for granted (Luper-Foy 1990).

Naturalized philosophy of science

Naturalized philosophy of science is part of a general programme of naturalism in philosophy. Naturalists reject all forms of supernaturalism, holding that reality, including human life and culture, is exhausted by what exists in the causal order of nature. Naturalists also reject any claims to a priori knowledge, including that of principles of inference, holding instead that all knowledge derives from human interactions with the natural world. Philosophically, naturalists identify most closely with empiricism or pragmatism. David Hume was a naturalist. So was John Dewey. The logical empiricists were naturalists regarding fundamental ontological categories such as space, time and causality, but non-naturalists about scientific inference, which they came to regard as a branch of logic. Most naturalists now dismiss searches for 'philosophical foundations' of the special sciences, treating the basic principles of any science as part of scientific theory itself.

The main objection to naturalism has been at the level of general methodological principles, particularly those regarding scientific inference. Here non-naturalists object that, being limited to 'describing' how science is in fact practised, naturalists cannot provide norms for legitimate scientific inferences. And providing such norms is held to be one of the main goals of the philosophy of science. Naturalists reply that the only norms required for science are those connecting specific means with the assumed goals of research. These connections can be established only through further scientific research. And the choice of goals is, for naturalists, not a scientific question but a matter of practical choice guided by an empirical understanding of what can in fact be achieved.

Among naturalists, the main differences concern the relative importance of various aspects of the practice of science. These aspects exist at different levels: neurological, biological, psychological, personal, computational, methodological, social and cultural. Each of these levels has its champions among contemporary naturalists, some insisting that everything ultimately be reduced to their favourite level. Perhaps the wisest approach is to allow that influences at all levels are operative in any scientific context, while admitting that some influences may be more important than others in particular cases, depending on what one seeks to understand. There may be no simple, one-level, naturalistic theory of science.

1 Naturalism and the philosophy of science

Philosophical naturalism is the view that an adequate philosophical account of the natural world, including humans, can be given solely in terms of objects and processes occurring in the natural causal order. No appeal to anything supernatural or transcendent is required. Materialism and other forms of reductionism imply naturalism, but naturalists need not be reductive materialists. Thus a naturalist might deny the reducibility of psychology to biology so long as psychology itself functions as a natural science in its methods and forms of explanation (see Reduction, problems of; Unity of science).

Naturalism is not new. David Hume was clearly a naturalist in holding that the operations of the mind could be understood solely in terms of natural processes such as perception, memory and the association of ideas. His goal has been rightly characterized as that of becoming the Newton of the mind. J.S. Mill continued the naturalist tradition in Britain. Descartes, on the other hand, counts as a non-naturalist because his theory of knowledge required an immaterial soul with special powers for ascertaining truths involving clear and distinct ideas. Kant was a more sophisticated non-naturalist. For Kant the operations of individual minds take place in the causal order of appearances. But all perception and judgment is constrained by categories that are discoverable only by the special philosophical method of transcendental deduction. In the mid-nineteenth century, other German scientist-philosophers, such as Hermann Helmholtz attempted to naturalize Kant's categories, particularly those pertaining to spatial perception, through physiological and psychological investigations.

The late nineteenth-century debate in Germany between naturalists and non-naturalists was echoed in the USA where philosophers also attempted to assimilate the findings of the sciences, particularly psychology. John Dewey exemplified this debate within his own philosophical development. Beginning as a Hegelian who saw psychology as applying only to individuals while philosophy uncovered the universal laws of rational thought, Dewey ended up a pragmatic naturalist who looked to science for all knowledge of the world and to philosophy primarily for investigation into the social values that should direct the employment of scientific knowledge for human betterment.

The non-naturalist cause found a major champion in Gottlob Frege who, beginning in the 1880s, insisted on a sharp distinction between patterns of inference actually employed by individuals and objectively valid arguments. The former may be studied as part of empirical psychology; the later are the province of logic, an a priori discipline which is part of philosophy (see Frege, G. §4). Frege's views were incorporated into the programme of scientific philosophy promoted by the Vienna Circle led by Moritz Schlick and Rudolf Carnap, and by the Berlin Society for Scientific Philosophy led by Hans Reichenbach (see Vienna Circle §3). The major thrust of scientific philosophy was the naturalization of metaphysics, that is, the replacement of Neo-Kantian philosophical metaphysics with a scientific metaphysics. In particular, the fundamental properties of space, time and causality, they argued, cannot be learned through any sort of purely philosophical inquiry, but only through the study of the appropriate scientific theories, particularly relativity theory and the quantum theory (see General relativity, philosophical responses to §3). The task left to philosophy was the logical analysis of scientific theories, a purely a priori undertaking. Eventually included in this analysis was the *epistemological* relationship between statements of evidence and statements of theory. Following Frege, this came to be regarded as the logical study of inductively valid or rationally justified inference, independent of any inferences actual scientists might in fact make (see Inductive inference).

In the face of German National Socialism, most of the scientific philosophers left the German-speaking world and the vast majority, including Carnap and Reichenbach, ended up in the USA. Their incorporation into the American philosophical world was fostered primarily by pragmatist philosophers. By the mid-1950s, what in Germany had been a radically anti-establishment scientific philosophy had become in North America the established philosophy of science. Ironically, pragmatism and its associated naturalism were eclipsed by a rival empiricist programme incorporating a militantly non-naturalistic view of scientific method (see Pragmatism; Logical positivism §§3-4).

The revival of naturalism owes much to the works of Kuhn and Quine during the 1960s. In *The Structure of Scientific Revolutions* Kuhn attempted to explain the historical development of science in terms borrowed from fields such as linguistics, psychology, and sociology - a thoroughly naturalistic project. (see Kuhn, T.S. §2). Quine, by contrast, argued for a naturalized epistemology by demonstrating the impossibility of carrying out any programme of reducing all knowledge to sense impressions, a programme that had come to be synonymous with a Fregean approach to epistemology (see Quine, W.V. §2; Naturalized epistemology). Unfortunately, the empirical resources available in the 1960s, gestalt psychology, behaviourism and structural-functional sociology of science, were not sufficient to develop the naturalistic programmes of either Kuhn or Quine. Since the mid 1970s, however, developments in the cognitive sciences and constructivist sociology of science have provided far richer resources (see Constructivism). By the mid-1980s, a naturalized philosophy of science had become once again a viable option.

2 The problem of epistemic norms

The most persistent objections to the re-emergence of naturalism in the philosophy of science involve the status of epistemic norms, or principles of rational inference. The problem may be stated as follows: a naturalistic philosophy of science, it is said, can at most provide *descriptions* of actual scientific practice. But science requires *normative principles* which distinguish those claims legitimately warranted by available evidence from those not so warranted. So no naturalized philosophy of science can be a complete philosophy of science. A more pointed way of framing the same sort of objection is this: a naturalized philosophy of science appeals to established theories of various sciences. But one of the conclusions of any philosophy of science should be an account of what makes some theories warranted and others not. So a naturalized philosophy of science either begs a central question or remains viciously circular.

Naturalists respond to the more pointed objection by questioning the presupposition that it is possible to justify any principles of scientific inference a priori. Here naturalists can point to nearly 300 years of attempts by empiricist philosophers to find an adequate justification of induction that does not beg the question (see Induction, epistemic issues). Such considerations, of course, do not constitute an a priori proof that no such justification will ever be forthcoming. But where, the naturalist asks, might such a justification be found? In logic, in intuition,or in an a priori theory of human judgment? These have all been tried without acknowledged success. Where could we turn next? The naturalist concludes that there most likely is no place beyond the province of science that could provide such a justification. The supposition that there must be some such place looks to be the product of an unwarranted

yearning for some sort of absolute foundation for scientific claims.

Positively, naturalists recommend a non-foundational, pragmatic approach to epistemology. Individually and collectively we can do no better than begin where we are, with the theories and methods we have inherited, historically contingent though these may be. Any theory or method may be questioned, though not without a specific reason, and not all at once. The general goal is not to ground what we think we know, but to improve upon it. As for all-encompassing sceptical worries, naturalists take comfort in evolutionary biology. We as a species would not be here if our evolved sensory and motor skills were not good enough to secure the necessities of life and procreation. This reflection begs the question against a radical sceptic of course, and does little to explain how we achieved our current advanced state of scientific knowledge, including that of evolutionary biology. But it provides a naturalistic starting point.

As for the general problem of epistemic norms, naturalists insist that categorical principles of rational inference are not to be had. But that still leaves conditionally normative principles of the form: if you wish to accomplish goal *G*, try method *M*. The warrant for such principles consists in finding empirical evidence that doing *M* in fact promotes achievement of *G*. In this sense, all knowledge has potential normative implications, for example, as nuclear physics had implications for how to go about building a powerful bomb.

Contemporary naturalists disagree about the kind of principle to be sought, and the kind of evidence relevant to normative claims. Some, for example Larry Laudan, look for general methodological rules such as: successful prediction of novel facts provides stronger evidence for a theory than does explanation of previously known facts. And the relevant evidence is said to be found in historical instances in which theories which generated successful predictions turned out to be better than others which did not. Other naturalists doubt the usefulness of rules at this level of generality either for the practice of science or for explaining how science works. And they doubt that the historical record can in fact furnish the required evidence. Rather, it is argued, we need a deeper theory of how scientists do science and of the methods they employ. Such a theory could help us explain why some scientists were successful and others not. It could even provide some general normative guidance for scientists themselves, or for those who determine priorities for funding scientific research. And it could explain the circumstances in which more general rules, like that regarding the value of successful predictions, may be operative. The evidence for such a theory of science would have to go beyond mere correlation between supposed applications of a rule and the end results. It would be more like evidence which supports any general theory in such areas as biology, statistics, the cognitive sciences or sociology. Here it is important that statistics and experimental design be seen as themselves scientific theories relating experimental designs, experimental results, and correct decisions among alternative hypotheses.

Finally there is the question of the general epistemic goals of science. Naturalists reject attempts to determine a priori what the epistemic goals of science should be. They doubt there are any justifiable principles on which to base such attempts. Rather, we can investigate only what epistemic goals have in fact been pursued by various scientists and, perhaps, the empirical consequences of pursuing various goals. One need not presume that all scientists everywhere have pursued the same epistemic goals, or even that their professed goals are the same as their actual goals. Naturalists thus reject general philosophical arguments for or against ’realism’ or for or against ‘empiricism’ (see Scientific realism and antirealism §3). The historical record shows that scientists have pursued both sorts of goal, sometimes successfully and sometimes not.

3 The bases for naturalization

Naturalists differ among themselves mainly on the sorts of scientific knowledge they deem most relevant to a naturalistic understanding of science. Individual naturalists typically stress one type of knowledge over all others, and the types of knowledge tend to represent different levels of organization. Paul Churchland, for example, attempts to understand scientific explanation and theorizing at the neuro-computational level. Paul Thagard argues that conceptual revolutions can be explained by relationships of explanatory coherence among statements that can be modelled in a quasi-connectionist computer program. Many naturalists, following in the footsteps of Darwin himself, appeal to evolutionary biology, though in different ways (see Evolution, theory of). Michael Ruse thinks that evolution yielded general methodological rules we follow intuitively and discover by reflecting on our practice. David Hull (1988) argues for strict isomorphisms among organic evolution, the evolution of scientific communities, and the evolution of scientific concepts. Others, including Stephen Toulmin, Donald Campbell and

Abner Shimony make less strict use of evolutionary ideas in their philosophies of science. Still other naturalists, such as Nancy Nersessian, focus on concepts and results developed in cognitive psychology. Some would add here a theory of human judgment and experimental design. Finally, others, such as Steve Fuller, find the most explanatory power at the level of social interaction and communication. What is an aspiring naturalist to conclude?

The wise course is to recognize that there can be no such thing as a homogeneous theory of science. Science is far too complex a phenomenon for that. Rather, we must settle for a diverse set of models in terms of which we can understand how science works in specific instances. These models will be inspired by models first developed in a wide variety of sciences. The best to be hoped for is that the various models employed are complementary. Where applications overlap, the results should at least be compatible. But we must also realize that there is a limit to theoretical naturalistic explanations of science. Some features of various sciences will have no deeper explanation than the existence of various historical contingencies in their origin and development. As a human activity, even as an activity expressly designed to produce faithful representations of nature, science will always contain elements of historical contingency.

Nature and convention

The nature-convention distinction opposes instinctual or 'spontaneous' modes of comportment (those which follow from 'human nature') to those which are socially instituted or culturally prescribed. Its philosophic interest resides in its use to justify or contest specific forms of human behaviour and social organization. Since the 'conventional' is opposed to the 'natural' as that which is in principle transformable, the adherents of a particular order in human affairs have standardly sought to prove its 'naturality', while its critics have sought to expose its merely 'conventional' status. Relatedly, 'conventions' may be associated with what is distinctive to 'human', as opposed to 'bestial' nature, or denounced for their role in repressing our more 'natural' impulses.

The nature-convention antithesis is one of a number of cognate dualisms (nature-culture; natural-artificial; animal-human) through which Western thought conceptualizes what is distinctive to the 'being' of humanity, and demarcates between that which is independent of and pre-given to human activity and that which is humanly achieved or contrived. Though many would dispute whether any clear-cut division can be drawn between the 'human' and the 'animal', the very posing of the question of our affinity with or distinction from other creatures is reliant on a prior appreciation of those features which are specific to humans. One of the most notable of these is that human beings establish 'conventions': customs, rules, or norms of behaviour which are socially instituted as opposed to naturally dictated. The establishment of conventions is thus intimately bound up with those capacities for moral thought and action which mark us off from other animals. To follow (or contest) a convention presupposes an ability to understand prescription, and to act otherwise than in obedience to the dictate of instinct.

The nature-convention opposition has its origins in Greek antiquity, in the fifth century BC, where the distinction between *physis* and *nomos* becomes the site of a dispute about the cultural relativity of political and moral values (see Plato; Sophists) which has remained a central concern of philosophy ever since. Thus it is by reference to the multiplicity of human conventions, that relativists have often challenged claims about the existence of a common 'human nature' or universally applicable morality (see Relativism §1).

Conventions may be very culturally specific, transient, and readily transformed codes of conduct, or more perduring customs or institutional forms which are none the less particular to given societies. In some instances the conventional prescriptions or prohibitions may be trans-cultural and deeply entrenched (as in the case of the law against incest, which Claude Lévi-Strauss presents as marking the arrival of the 'cultural'), while remaining in principle revisable as norms of conduct precisely in virtue of their being humanly ordained.

It is the double association of the conventional both with what is 'right' for human beings and with what is transformable, and of the 'natural' both with the 'bestial' and with what is deemed immutable, which accounts for the complex ideological disputes that attach to the distinction. The rules that human beings set themselves (against murder, or incest, for example) have very frequently been viewed as preserving them from the degeneracy or 'wickedness' of nature's ways (a position argued very forcibly by John Stuart Mill in his essay 'Nature' (1874)). But in the Rousseauan or Romantic conception, nature is viewed as a source of goodness or authenticity, and hence invoked as a model from which humanity should take its cue. These differing perspectives, however, may both seek confirmation in terms that tend to blur or confound the nature-convention distinction: those forms of behaviour which distinguish us from the beast being endorsed as qualities of human nature (and hence denied the status of 'mere' convention); and those which nature inspires being pitted against those supposedly natural rules of conduct which it is claimed are more properly to be viewed as repressive convention.

The philosophic interest of the nature-convention distinction lies therefore in the normative disputes that are conducted in its terms: that which is socially instituted is at once both defended by its adherents as part of the order of nature, and thus untransformable, and exposed by its critics as conventional and hence mutable. Relations of class, and discriminations on grounds of gender, race and sexuality, for example, have all been said to be natural by those seeking to sustain their social hierarchies, and denounced as illegitimate and oppressive norms by those seeking to overthrow them. Within this challenge, however, to the naturalization of what is socially instituted, we may distinguish between those who would contest what is said to be natural in the name of the more authentic naturality of what they seek to institute; and those (like Michel Foucault) who would insist upon the always normative and constantly revisable quality of what is said to be natural to human societies at any point in time. For

example, one may contest existing social relations, institutions and sexual 'norms' in terms of their 'alienation' from or 'repression' of nature, or dispute the very existence of natural, as opposed to socially 'constructed' or inculcated needs and desires. It is arguable, however, that without recourse to an idea of nature there can be no coherent or self-consistent critique of custom or convention.

Nature, aesthetic appreciation of

In the Western world, aesthetic appreciation of nature and its philosophical investigation came to fruition in the eighteenth century. During that time, aestheticians made nature the ideal object of aesthetic experience and analysed that experience in terms of disinterestedness, thereby laying the groundwork for understanding the appreciation of nature in terms of the sublime and the picturesque. This philosophical tradition reached its zenith with Kant, while popular aesthetic appreciation of nature continued primarily in terms of the picturesque.

In the late twentieth century, renewed interest in the aesthetics of nature has produced various positions designed to avoid assimilating appreciation of nature with traditional models for aesthetic appreciation of art. Three are especially noteworthy. The first holds that the appreciation of nature is not in fact aesthetic; the second rejects the traditional analysis of aesthetic experience as disinterested, arguing instead that the aesthetic appreciation of nature involves engagement with nature; the third attempts to maintain the traditional analysis, while distinguishing aesthetic appreciation of nature by dependence on scientific knowledge.

These positions have a number of ramifications. In freeing aesthetic appreciation of nature from artistic models, they pave the way for a general environmental aesthetics comparable to other areas of philosophy, such as environmental ethics. Moreover, the significance given to scientific knowledge in the third position both explains the aesthetic appreciation associated with environmentalism and provides aesthetic appreciation of nature with a degree of objectivity that may make aesthetic considerations more effectual in environmental assessment.

1 History

Although a tradition of viewing art as the mirror of nature has existed since antiquity, the idea of aesthetically appreciating nature itself is sometimes traced toPetrarch's novel passion for climbing mountains, simply in order to enjoy the prospect. Yet from the dawn of the Renaissance to the present, the development of aesthetic appreciation of nature has been uneven and episodic. Initially such appreciation, together with its philosophical investigation, was hamstrung by a religious tradition that saw mountains as despised heaps of wreckage left behind by the flood, wilderness regions as fearful places for punishment and repentance, and all of nature's workings as a poor substitute for the perfect harmony lost in humanity's fall. It took the rise of a secular science and an equally secular art to free nature from such associations and open it up for aesthetic appreciation. Thus, in the Western world, the evolution of aesthetic appreciation of nature has been intertwined with the objectification of nature achieved by science and the subjectification of it completed by art.

Early in the eighteenth century, British aestheticians initiated a tradition that gave theoretical expression to the connection between aesthetic appreciation of nature and scientific objectivity. Empiricist thinkers, such asJoseph Addison and Francis Hutcheson, took nature rather than art as the ideal object of aesthetic experience and developed the notion of disinterestedness as the mark of such experience. In the course of the century, this notion was elaborated so as to exclude from aesthetic experience an ever-increasing number of associations and conceptualizations. Thus, the objects of appreciation favoured by the tradition - British landscapes - were eventually severed not only from religious associations, but from an appreciator's personal, moral and economic interests. The upshot was a mode of aesthetic appreciation that looked upon the natural world with an eye not unlike the distancing, objectifying eye of science. In this way, the tradition laid the groundwork for the idea of the sublime, by which even the most threatening of nature's manifestations, such as mountains and wilderness, could be distanced and appreciated rather than simply feared and despised (see Sublime, the §§2-3).

However, if disinterestedness laid the groundwork for the sublime, it also cleared the ground for another, quite different idea: the picturesque. This idea secured the connection between aesthetic appreciation of nature and the subjective renderings of nature in art. The term literally means 'picture-like' and indicates a mode of appreciation in which the natural world is divided into scenes, each aiming in subject matter or in composition at an ideal dictated by art, and especially by poetry and landscape painting. Thus, while disinterestedness and the sublime stripped and objectified nature, the picturesque dressed it in a new set of subjective and romantic images: a rugged cliff with a ruined castle, a deep valley with an arched bridge. Like disinterestedness, the picturesque had its roots in the theories of early eighteenth-century aestheticians, such as Addison, who thought 'works of nature' more appealing the more they resembled art. The trend of the picturesque culminated later in the century, when,

popularized primarily by William Gilpin and Uvedale Price, it became the aesthetic ideal of English tourists as they pursued picturesque scenery in the Lake District and the Scottish Highlands. Indeed, the picturesque remains the preferred mode of aesthetic appreciation for the form of tourism that sees the natural world in the light of travel brochures, calendar photos and picture postcards.

While the picturesque lingered on as a popular appreciative mode, theoretical study of the aesthetics of nature, after flowering in the eighteenth century, went into decline. Many of the main ideas, such as disinterestedness and the centrality of nature rather than art, reached their climax withKant (Sublime, the §3), and in his third critique these ideas received such exhaustive treatment that a kind of closure was achieved. In the new world order initiated by Hegel, art was a means to the Absolute, and it, rather than nature, was destined to became the favoured subject of philosophical aesthetics.

2 Background to the present

However, as theoretical study of the aesthetics of nature declined, a new view of nature was initiated that eventually gave rise to a different kind of aesthetic appreciation. This mode of appreciation was rooted in the nature writings of Henry David Thoreau and reinforced by George Perkins Marsh's recognition that humanity is the major cause of the destruction of nature's beauty. It achieved its classic realization at the end of the nineteenth century in the work of the American naturalist John Muir.Muir saw all nature and especially wild nature as aesthetically beautiful and found ugliness only where nature was subject to human intrusion. These ideas strongly influenced the North American wilderness preservation movement and continue to shape the aesthetic appreciation of nature associated with contemporary environmentalism. This kind of appreciation may be called positive aesthetics and, in so far as it eschews humanity's marks on the landscape, contrasts sharply with picturesque appreciation, with its delight in the signs of human presence. It became and remains the rival of the picturesque as the popular mode of aesthetic appreciation of nature, although popular appreciation is typically an uneasy balance of the two.

In spite of these developments in popular appreciation of nature, however, philosophical aesthetics, with few exceptions, ignored nature during the nineteenth and much of the twentieth centuries. Friedrich Schelling and a few thinkers of the Romantic movement dealt with it to some extent, and George Santayana and John Dewey both discussed it. But, by and large, aesthetics was dominated by an interest in art. By the mid-twentieth century, philosophical aesthetics in the analytic tradition was virtually equated with philosophy of art. Moreover, when aesthetic appreciation of nature was mentioned, it was treated, by comparison with that of art, as a messy, subjective business of little philosophical significance. In this context Ronald Hepburn's work in the 1960s had special importance. Hepburn argued that aesthetic appreciation of nature was as significant and as rich as that of art, and that it could be, though not a carbon copy of appreciation of art, similar to that of art - shallow or deep, appropriate or not. It required serious philosophical study.

3 Positions and problems

In the latter part of the twentieth century, renewed interest in the aesthetics of nature has generated a number of different positions on aesthetic appreciation of nature. Many of them share the view that such appreciation cannot simply be assimilated with standard accounts of aesthetic appreciation of art. In this they affirmHepburn's insight that the appreciation of nature, although comparable to that of art, does not mimic it. The rejection of some of the traditional modes of aesthetic appreciation is implied. For example, it is argued that appropriate appreciation of nature cannot involve viewing natural objects in the same way that we frequently view traditional art objects such as works of sculpture - that is, as passive objects of contemplation divorced from both their and our spatial and temporal contexts. By contrast, natural objects belong in an environment that not only surrounds and engages them, but surrounds and engages the appreciator. Thus, the physical or contemplative removal of natural objects or ourselves from their environments results in inappropriate appreciation. Likewise, it is held that viewing nature as we might view a landscape painting, that is, as a static scene that we behold from a predetermined distance, is equally inappropriate in that it misleadingly reduces nature to a series of two-dimensional scenic views.

Given the rejection of traditional modes of aesthetic appreciation of nature, an alternative approach becomes necessary. The most radical of such alternatives elevates the neglect of nature by analytic aesthetics to a philosophical position, denying either implicitly or explicitly the possibility of aesthetic appreciation of nature.

When explicitly developed, this position leaves traditional modes of appreciation intact for art, but concerning nature argues as follows: aesthetic appreciation necessarily involves aesthetic judgment, which entails judging the object of appreciation as the achievement of a designing intellect. However, since nature is not the product of a designing intellect, appreciation of it is not aesthetic. In the past, the appreciation of nature was deemed aesthetic only because of the assumption that nature is the handiwork of a designing creator; this assumption is either false, or at least inadequate for grounding an aesthetic of nature. This position is problematic, however, since it runs against both the orthodox view that everything is open to aesthetic appreciation and the common-sense idea that at least some natural objects, such as certain landscapes and sunsets, constitute paradigm objects of aesthetic appreciation.

A second alternative rejects traditional modes of aesthetic appreciation not only for nature but for art as well. This position argues that the disinterestedness tradition involves a mistaken analysis of the aesthetic and that this is most evident in the field of aesthetic appreciation of nature. In such appreciation the quality of disinterestedness, with its isolating, distancing and objectifying gaze, is out of place, for it is the means by which both natural objects and appreciators are wrongly abstracted from the environments in which they properly belong and in which appropriate appreciation is achieved. Thus, this position replaces disinterestedness with engagement, distance with immersion, and objectivity with subjectivity, and calls for a new aesthetic of engagement. Such an aesthetic, it is argued, yields a mode of appreciation not only more appropriate for nature, but also for most works of art, at least for those of the twentieth century. However, this second position is also problematic. First, since disinterestedness constitutes the favoured analysis of the aesthetic, its rejection may constitute a rejection of the aesthetic itself, reducing this second alternative to a version of the first. Second, this position seemingly embraces an unacceptable degree of subjectivity in aesthetic appreciation of both nature and art.

A third position attempts to maintain much of the traditional analysis of the aesthetic, while yet accommodating features unique to nature. The motivation for this alternative is not only to find a mode of aesthetic appreciation especially appropriate for nature, but also to avoid excessive subjectivity. This position notes that in aesthetic appreciation of art both appropriateness of appreciative mode and objectivity are achieved by tying appreciation to understanding in terms of art-historical and art-critical knowledge. It thus adopts a parallel approach for aesthetic appreciation of nature. However, although the appropriate knowledge for art is derived from art history and art criticism, nature is not art and such knowledge is not relevant to nature's appreciation. For nature, it is argued, the relevant knowledge is that which provides our understanding of the natural world, that is, the knowledge given by the natural sciences. For example, just as art-historical knowledge of mid-twentieth century schools of painting endows appreciation of an abstract expressionist work with appropriateness and objectivity, so knowledge of geology, biology and ecology similarly endows appreciation of an alpine meadow. In this way, aesthetic appreciation of nature is once again linked to the objectifying eye of science.

Like the other two alternatives, however, this third alternative faces some philosophical difficulties. One is that a scientific approach may not yield real aesthetic appreciation. However, unlike the second alternative, the third position does not reject traditional resources, such as disinterestedness, as constitutuents of aesthetic appreciation. Thus, a science-based mode of appreciation can be sufficiently disinterested to be truly aesthetic. Indeed, the problem may be the opposite one, that such a mode of appreciation, given its essential dependence on science, is too distancing, too objectifying. It thus runs the risk of wrongly abstracting natural objects from their environment and in this way making appropriate appreciation impossible. In reply it is argued that since aesthetic appreciation necessarily involves distancing and thus some degree of abstraction, the issue is not whether to abstract. Rather it is how to supplement the required abstraction so as to achieve rich and appropriate appreciation. The problem with traditional approaches is not that they involve abstraction, but that, having abstracted nature, they reconstitute it by means of artistic models, such as the picturesque, and not in terms of relevant knowledge, such as science provides. Moreover, science is not, or at least is no longer, the severely abstracting endeavour it is popularly taken to be. Modern natural science, as exemplified by ecology, increasingly views nature in holistic terms.

4 Ramifications

These approaches to the aesthetics of nature have a number of ramifications. One is that, concerning popular appreciation of nature, they seemingly support positive aesthetics as opposed to the picturesque. Appreciating nature in terms of artistic models, such as the picturesque, is rejected by all these approaches, and the scientific

approach in particular accords well with the positive aesthetic model. When nature is aesthetically appreciated in virtue of natural science, positive aesthetic appreciation seems singularly appropriate, for, on the one hand, humanity's marks on the landscape appear especially out of place, while, on the other, wild, pristine nature becomes an aesthetic ideal. Moreover, as the natural sciences increasingly find, or at least appear to find, unity, order and harmony in nature, nature itself, when appreciated in the light of such knowledge, increasingly appears more profoundly beautiful. Science replaces the once despised wreckage of God's deluge with inspiring manifestations of orderly geological forces; and the harmony lost in humanity's fall is superseded by a perfect harmony of science's own making.

Two other ramifications concern aesthetics and philosophy more generally. First, all three positions (and particularly the scientific approach), in rejecting artistic models for appreciation of nature and in replacing them with a dependence on knowledge of the object of appreciation, provide a blueprint for aesthetic appreciation in other non-art cases. It is made evident that in aesthetic appreciation of, for example, toys, furniture, people, cornfields, pets, neighbourhoods, shoes and shopping malls, what is appropriate is not an imposition of various artistic models, but rather a dependence on knowledge that is pertinent to the nature of the object of appreciation. This suggests a general and universal aesthetics, which may be termed environmental aesthetics, distinct from traditional aesthetics, which is too easily equated with philosophy of art. Second, there is an alignment of this universal aesthetics with other areas of philosophy in which there is a rejection of archaic, inappropriate models and a new-found dependence on knowledge relevant to the particular objects in question. For example, environmental aesthetics parallels environmental ethics in its rejection of anthropocentric models for the moral assessment of the natural world, replacing them with models based on science, most notably ecology (see Environmental ethics).

Lastly, if approaches such as the scientific one described above endow aesthetic appreciation of nature with a degree of objectivity, they might have some practical relevance in a world increasingly engaged in landscape and environmental assessment. Individuals making such assessments are often reluctant to acknowledge the importance of aesthetic considerations, regarding them at worst as totally subjective or based at best on culturally relative artistic modes of appreciation. A scientific approach suggests the need to re-evaluate such opinions.

Naturphilosophie

Naturphilosophie *refers to the philosophy of nature prevalent especially in German philosophy, science and literary movements from around 1790 to about 1830. It pleaded for an organic and dynamic worldview as an alternative to the atomist and mechanist outlook of modern science. Against the Cartesian dualism of matter and mind which had given way to the mechanist materialism of the French Encyclopedists, Spinoza's dual aspect theory of mind and matter as two modes of a single substance was favoured. The sources of this heterogeneous movement lie in the philosophy of German idealism as well as in late classicism and Romanticism. The leading figure, Schelling, assimilated and stimulated the major trends and ideas through his work.*

After the death of Hegel (1831) and of Goethe (1832), Naturphilosophie *quickly disappeared from the mainstream. Yet it survived in various different forms, especially as an undercurrent of German culture and science, until the twentieth century.*

1 Kant and Fichte

The leading role among the various trends in *Naturphilosophie* was played by Schelling's philosophy of nature. To understand it, it is necessary to examine also the philosophy of Kant and subsequently that of Fichte.

Kant had a threefold influence on the movement of *Naturphilosophie*: through his *Metaphysische Anfangsgründe der Naturwissenschaft (Metaphysical Foundations of Natural Science)* (1786) where he took forces as the defining properties of matter; through his third critique, the *Kritik der Urteilskraft (Critique of Judgment)* (1790), where he treated the concept of purpose in nature, and finally in providing a frame for these ideas through the transcendental idealism of his first critique, the *Kritik der reinen Vernunft (Critique of Pure Reason)* (1781/87).

In his *Metaphysical Foundations* Kant tried to clarify the concept of matter as it has to be presupposed by all possible scientific investigation. In contesting Newton's views, he saw matter as constituted by the opposing forces of attraction and repulsion. Matter fills space by its repulsive force. The resulting dispersion is counteracted and limited by an attractive force. Thus Kant arrives at a dynamic view of matter which takes active opposing forces as fundamental and which avoids the conception of the atom and of empty space. His theory advanced a dynamic view of nature ('dynamism') as a research programme in physics, and made similar conceptions of the sciences appear in a new light (for example, positive and negative forces in magnetism and electricity).

In the *Critique of Judgment*, Kant tried to come to terms with the teleological structure of nature. Organisms as products of nature cannot be completely explained in the causal way in which one would explain a mechanical system. For in organisms not only do the parts determine the whole, but the purpose guiding the organism as a whole also determines its parts. In understanding organism and nature as a whole we have thus to grasp it as fulfilling a purpose, to see it as a self-organizing system which has the cause and effect of its action in itself (Kant 1790: §64). However, since we can talk of purposes only in relation to free action and since nature is not an intelligent being we can ascribe purposes to nature only in a metaphorical, regulative sense, *as if* it were a free acting creature with its own purposes. Our grasp of organic nature is therefore inherently subjective and can never reach the objective validity of explanations by mechanical causality. Later *Naturphilosophen* attempted to overcome this Kantian limitation and to furnish nature with an objective, purposive structure which is constitutive of it, and thus to see nature as an autonomous and even indeterministic system.

In the *Critique of Pure Reason*, Kant had claimed that experience is not passively received by our mind but is determined and even produced by categories intrinsic to our own understanding. The unity of our self-consciousness, the synthetic apperception, as the 'highest point' of philosophy is responsible for our sense impressions being synthesized into genuine knowledge. Thus every philosophy has to start with an inquiry into the transcendental conditions of the mind itself which make knowledge possible.

Before he became acquainted with Kant's writings, Johann Gottlieb Fichte believed determinism to be unavoidable. His view changed dramatically, however, when he realized that Kant's transcendental idealism can be radicalized so as to make room for absolute human freedom. Nature is a system of necessity only because it is conceived by us that way. In Kant, the unity of self-consciousness was only the *formal* condition of our knowledge; some material must be given to our senses which ultimately stems from the thing-in-itself. For Kant,

the process of being affected by objects does not depend on the self. Fichte, however, came to reject the idea of the thing-in-itself and claimed that the unity of self-consciousness is also the *material* condition of our knowledge. The self with its capacity for synthesizing knowledge is not reacting to something given, it is autonomously producing its reality, including itself. Knowledge of objects is derived from an initial act of self-positing; objects are the result of a law-governed production of the ego. The ‘I’, the self, is in this case not to be thought of as the consciousness of an individual person, but as a general structure independent of individual realization.

2 Schelling and the *Naturphilosophen*

Schelling originally started in complete harmony with Fichte’s viewpoint, but later gradually shifted away from it. Whereas Fichte stressed the certainty of which the I disposes in positing itself, Schelling tried to uncover the origin of the I, the kind of being from which it stems. ‘*I am*! My I comprises a being which precedes all thinking and conceiving’ (Schelling [1795] 1856-61, vol. 1: 167). This being is now seen as more comprehensive than the ego: namely nature. The I is not its own product, as Fichte would have it, but the I and the material objects are produced by nature as a ground deeper than the I. ‘Nature’s reality stems from herself - she is her own product - a whole which is organized out of itself and organized by itself’ (Schelling [1799] 1856-61, vol. 3: 17). With this move, Schelling could ascribe to nature the structure which Fichte had claimed for the I. Schelling also thought that this would make it possible to overcome the limitations which Kant thought were necessary in our grasp of nature. Nature can now be seen as a reality which is a self-determining system for which purpose is a constitutive idea and not a regulative one as Kant had it.

From 1797 to 1806 Schelling made various attempts to formulate his philosophy of nature. This necessarily brought him into conflict with Fichte’s soulless mechanical conception of nature. For Fichte nature was just the ‘system of necessity’, the inanimate realm of the ‘not-I’ or ‘non-ego’, posited by the I itself. Schelling, however, envisaged nature as a vital process from whose activity the consciousness of the ego and the mind emerges. Whereas Fichte asked how the self gets at nature, Schelling had the problem of how nature finally arrives at the I.

At the beginning of his development away from Fichte, Schelling envisaged *Naturphilosophie* as being of equal status with transcendental philosophy; from 1801 onwards, however, *Naturphilosophie* became primary for Schelling and independent from it. He claimed that we cannot grasp nature by merely investigating her products as they present themselves to our experience. This would be to see nature merely as an inanimate object, as *natura naturata*. Nature as ‘productivity’, or ‘absolute activity’, in its ‘infinite becoming’ requires studying her as *natura naturans*, as a subject, a productive process which eventually gives rise to mind and crystallizes in its products (Schelling [1799] 1856-61, vol. 3: 284). This view eventually flowed into a critique of Newtonian mechanical physics taken as the paradigm of modern science. Mechanism starts from material bodies which are supposed to have the property of attracting and/or repulsing each other. Yet, in order to conceive nature as an entity that is able to produce the self and the objects in like manner, it is necessary to give attraction and repulsion a more basic status and to take them as defining properties from which material objects and also consciousness are derived. Schelling did not attack the experimental and empirical side of science but its premature objectivism which leaves out the subjective element in nature and its developmental aspect.

In carrying out his programme Schelling was influenced by the experimental physicist and founder of electrochemistry, Johann Wilhelm Ritter (1776-1810), and influenced him in turn. Ritter pleaded for a strong connection of galvanism and chemistry and saw the living organism as a system of nested galvanic chains. When he found that the galvanic process is not necessarily bound to organic material, he considered galvanic action to be the key to the activity of the whole universe.

Hegel was the other post-Kantian idealist who occupied himself with *Naturphilosophie*. He was decisively stimulated by Schelling before he came to work out a fundamentally different system. For Hegel, nature as the realm of the idea in its otherness is not to be grasped as an evolutionary process but as a conceptual development of the idea on the way to self-knowledge.

3 Major doctrines of *Naturphilosophie*

Schelling’s *Naturphilosophie* set the tone for many similar undertakings. Although these attempts sometimes differ very much in detail from each other, we can distinguish several recurrent tenets. First, and foremost, there is the

view of the 'unity of mind and matter'. Schelling and many *Naturphilosophen* argued that nature is animated, that there is an original unity or 'identity' of nature and mind which allows us to infer nature's laws from the laws of the mind and vice versa: 'The system of nature is at the same time the system of our mind' and 'Nature must be visible spirit, and mind invisible nature' (Schelling [1797] 1856-61, vol. 2: 39, 56). This view was primarily directed against both Cartesian dualism and eighteenth-century materialism. It had a great impact on the Romantic movement, both in literature and science. Hans Christian Ørsted, for example, who discovered electromagnetism in 1820, claimed that all objects are materialized ideas. And according to the biologist Lorenz Oken, it was the task of *Naturphilosophie* 'to show that the laws of the mind are not different from the laws of nature but that both represent each other. Philosophy of nature and philosophy of mind range, therefore, parallel to each other' (Oken 1843: §13). Later, one of the sharpest critics of *Naturphilosophie*, Hermann von Helmholtz saw the principal error of this movement precisely in the mingling of the necessary laws of nature with the spontaneous activity of mind. A last remnant of the identity view of nature and mind can be found in the dual aspect view of mind and body as it was embraced by a large number of physiologists, psychologists and many philosophers up to and including Rudolf Carnap's *Der Logische Aufbau der Welt (The Logical Construction of the World)* (1928).

A second doctrine is the prevalence of the organism as an explanatory model. For Schelling (as for Kant), mechanical explanations of nature have to be supplemented by organic ones. It is not possible, Schelling claimed, for the universe to be simply a causal mechanism as its organic structure is logically prior to its mechanical one. 'One and the same principle' is at work in both organic and inorganic nature which binds all of it 'into a general organism' (Schelling [1798] 1856-61, vol. 2: 350). Organisms are causally self-contained, they are their own cause and effect and they are self-movable, whereas causal mechanisms can only be moved from the outside and are therefore essentially passive. Carl Friedrich Kielmeyer, who decisively influenced Schelling in his organic thought, explained the organism in terms of three organic forces: irritability, reproduction and sensibility (Kielmeyer 1793). Irritability is organic activity or movement, sensibility is organic receptivity or sensation, and reproduction refers to the metabolism, to growth and procreation.

A third related doctrine of *Naturphilosophie* is the unity of nature and its forces, and thereby also of science. There was a strong tendency to exhibit nature in all its different aspects as a development from a small number of fundamental forces. Ørsted, whose dissertation had examined Kant's *Metaphysical Foundations of Natural Science*, had claimed that there is a 'unity of all the forces' of heat, chemistry, electricity and magnetism and that 'the former physical results [*Kenntnisse*] thus combine into a physics of one piece' (Ørsted 1803: 209). Similar claims have been made by scientists such as Faraday, Mohr, Grove, J. R. Mayer and others, which eventually led to the establishment of the energy conservation principle. The inorganic as well as the organic realms were seen as directed by the same principles, so that there is no essential difference between them. This does not mean that nature reduces to mechanism, but that the inorganic world has to be conceived as the product of an inherent organic natural process. *Naturphilosophie* developed the tendency to impose the organic categories found in the study of nature even on culture, society and the state. In this sense, it also helped to prepare the ground both for the later materialist and naturalist movement as well as for organic conceptions of the state and society.

In viewing nature as a unity, the movement of *Naturphilosophie* was also influenced by Goethe's search for an underlying idea of the organic and inorganic realms of nature. In morphology, he argued that all plants are modifications of one primordial plant, the *Urpflanze*, and that all plant organs were variations of a single fundamental organ, the leaf (see Goethe, J.W. von §3).

Another doctrine of *Naturphilosophie* concerns the developmental aspect of nature. Instead of viewing nature and its parts in static terms, *Naturphilosophie* tried to conceive of it as the outcome of an evolutionary graduated succession. Very often this process was seen as being initiated and maintained by a polar antagonism of forces. Models for conceiving this process were either taken by way of analogical reasoning from some philosophical source (Kant's *Metaphysical Foundations*, Fichte's idea of the self determining itself by positing the I and the not-I at the same time) or some scientific theory of the time (magnetism, galvanism, electricity, chemistry, physiology). Other sources included Goethe and Herder who also held influential theories of development. In all this, the concept of polarity played a prominent role and was seen as the continuous principle for every development and activity. Oken, for example, viewed living organisms as governed by two opposing processes: an individualizing one which increases the organism's vitality, and a universalizing one that leads to death and is a drive to the absolute (see Absolute, the).

Necessary being

Many think that God is perfect, or free from defect, and that being able not to exist is a defect. These infer that God is not able not to exist - that is, that God exists necessarily. Some add that what makes God perfect also makes him exist necessarily, and so trace his necessity to his immateriality (Aristotle), eternity (Plotinus) or simplicity (Aquinas). Others trace God's necessity to his relation to creatures (Ibn Sina, Anselm). Spinoza and Leibniz held that what makes God necessary explains his very existence.

Many have thought that if God exists necessarily, there is a sound ontological argument for God's existence, or that if there is a sound ontological argument for God's existence, God exists necessarily. But both claims are false. Some have used philosophical views of the nature of necessity - for example, that all necessity is conventional, a matter of how we choose to use words - to challenge God's necessary existence. But the theories which best support these challenges have fallen from favour, and in fact, even if one accepts the theories, the challenges fail.

1 Contingent and necessary existence

Our lives depend on many things. Had our parents not had us, we would not exist. Were there not enough food, or had we the bad luck to be there when a bomb goes off, we would not continue to exist. Our lives are thus contingent on parents, food and other things. To be contingent in this way is to be vulnerable. Such vulnerability seems a defect. So if we think God perfect, we will deny that God exists contingently.

If God exists and does not exist contingently, then:

(GN) God exists necessarily.

Thus (GN) emerges when we think about God's perfection. (GN) asserts that God exists, could not have failed to exist and cannot fail to exist. Equivalently, (GN) asserts that God exists and would always exist, no matter what. One can read (GN) as:

(GN1) the proposition 'God exists' is necessarily true,

or

(GN2) there necessarily is some individual or other who is God,

or

(GN3) whoever is God exists necessarily,

or

(GN4) the individual who is God exists necessarily.

If

(GN5) whoever is God is necessarily God

is false, (GN1) and (GN2) are equivalent, but logically independent of (GN3) and (GN4), and (GN3) entails (GN4), but (GN4) does not entail (GN3). If (GN5) is true, (GN1)-(GN4) are equivalent.

(GN) uses the concept of necessity. So as philosophers' grasp of necessity changed, what they meant by (GN) changed. But the impulse to ascribe maximal perfection to God always pushed towards claiming for God's existence the strongest sort of necessity a philosopher's modal theory would allow. Sometimes stronger doctrines of divine necessity subsume weaker ones; for instance, a God necessary in Leibniz's sense is also necessary in Aristotle's.

2 The evolution of divine necessity

Aristotle (§16) held that God exists throughout infinite time (*Metaphysics* XII, 7), and that:

(1) if something exists throughout infinite time, it exists necessarily (*Generation and Corruption* II, 11).

Aristotle rests (1) on a claim that any *x* is possibly *F* only if something is able to make it *F*, and a principle of plenitude, that any genuine ability (at least of certain sorts) sooner or later is used (*On the Heavens* I, 11). Thus for Aristotle, if a thing can cease to exist, it sooner or later does so. So if something exists throughout infinite time, it must be unable to cease to exist. A thing which exists and cannot not exist exists necessarily. Aristotle thinks that God's immateriality explains his necessity (*Metaphysics* XII, 6): things can cease to exist only if made of matter, for a thing *A* ceases to exist only if the matter making up *A* loses the constituting ('substantial') form whose presence in that matter makes *A* exist.

Plotinus (§3) asserts (GN) of *Nous*, a being like Aristotle's God (*Enneads* VI). *Nous* is atemporal due to its fullness and perfection of being (*Enneads* III). So *Nous* has no potentialities, since potentialities for Plotinus as for Aristotle are abilities to *become* different and so require time to be actualized (*Enneads* II). If *Nous* has no potentialities, it has no potentiality not to exist, and so exists necessarily.

Ibn Sina (§5), by contrast, held that (GN) 'means that God is a being without a cause, and…is the cause of other than himself' (*al-Risalat al-'arshiya*, 1951: 32). Other Muslim and Jewish philosophers added that God needs no cause or cannot be caused to exist. So read, (GN) does not entail that God or God's nature explains God's existence, or that anything explains God's existence, or therefore that there is an explanation for the fact that there is something rather than nothing at all.

This remains true even for Aquinas (§11), who held that 'God exists' is 'self-evident in itself' (*Summa theologiae* Ia, 2, 1), a status which entails broadly logical necessity. For that 'God exists' is self-evident in itself entails only that its truth would be self-evident to one who perceived God's nature, not that the perceiver would see why it is true or that God's nature would explain that truth. For Aquinas, 'God exists' is 'self-evident in itself' due to the doctrine of divine simplicity (see Simplicity, divine §§1-2). Given God's simplicity, God, his nature and his existence are identical (*Summa theologiae* Ia, 3, 3 and 4). If:

(2) God = God's existence,

Aquinas reasons, the subject and predicate of 'God exists' have the same reference. Thus 'God exists' is in effect an identity-claim, 'self-evident in itself' as all identities are: 'the reason for the necessity of God's existence is that His essence is His existence' (*Quaestiones disputatae de veritate*, 3, 1, *ad*. 7).

Thus Aquinas in effect traces God's necessity of existence to the necessity of identity. The necessity of identity is logical: statements of the form '$A = A$' instance the logical law of identity $(\forall x)(x = x)$, and so their contradictories are inconsistent with theorems of logic. Therefore even if Aquinas did not have this concept of necessity or mean to ascribe it to God, there is a sense in which, for Aquinas, God's existence is logically necessary. It may be that this holds for divine simplicity's many earlier medieval friends as well. Note that in Thomas' hands, (GN) does not *explain* God's existence. Divine simplicity makes (GN) true by entailing (2). But (2) *presupposes* that God exists. (If there is no Sherlock Holmes, 'Holmes = Holmes' is not true.) So divine simplicity and (GN) cannot explain God's existence.

Anselm's treatment of (GN) begins from the claim that God's will is the source of all necessity (*Cur Deus homo* II, 18). If it is, God's will makes God's existence necessary. How can it do so? To Anselm, 'necessarily, God is *F*' really says that nothing distinct from God can make it the case that God is not *F* (*Cur Deus homo* II, 18). If so, to Anselm, (GN) means 'nothing distinct from God can make it the case that God does not exist'. God makes this claim true if he creates only creatures who lack the requisite power, or if he does not create. For Anselm, what is so by necessity, properly speaking, is so because of compulsion, external constraint or some genuine inability (*Cur Deus homo* II, 5). So for Anselm, (GN) is an indirect way to say that God's power to exist cannot be overcome. For Aquinas, (GN) rests on something about God's own makeup. For Anselm, (GN) is true due to God's relations to creatures. For neither does (GN) explain God's existing (see Anselm of Canterbury §§2-4, 8).

Duns Scotus (§§7-11) popularized the view that a state of affairs is possible just in case it does not entail a contradiction, and is necessary just in case its negation entails a contradiction (*Commentaria oxoniensa* I, 36). This

view evolved into our current concept of broadly logical necessity. So like many writers after Scotus, Descartes took (GN) to assert God’s broadly logical necessity. Descartes held both the doctrine of divine simplicity and a theory of God’s responsibility for modal facts which may have been more radical than Anselm’s (see Plantinga 1980). So for Descartes, (GN) is overdetermined. As Descartes held that God causes the truth of logically necessary (‘eternal’) truths, being logically necessary did not for him entail being uncreated or wholly independent. Thus the meaning Descartes gave (GN) was wholly discrete from the meaning it had for such medievals as Ibn Sina.

In other Continental rationalists, (GN) also took on a new import. Spinoza (§§2-3) held that each existing thing’s existence must be explained (*Ethics* I, 8, n.2). In the case of God, who is necessarily uncaused, only his intrinsic nature can provide this explanation. So Spinoza infers that God’s nature entails and explains his existence (*Ethics* I, 11). Spinoza adds that ‘existence…insofar as it is conceived to follow necessarily from the definition alone of the [existing thing]…is conceived as an eternal truth’ (*Ethics* I, df.8). Spinoza’s eternal truths, like Descartes’, are broadly logically necessary. So for Spinoza, something exists necessarily only if and because its nature entails and explains its existence, and (GN) asserts or entails that such an explanation exists. Leibniz (§§3, 7) holds a principle of sufficient reason even stronger than Spinoza’s (1717: 16), and reasons much as Spinoza does (1697: 85-6). Neither Leibniz nor Spinoza held to divine simplicity as Aquinas and other medievals understood it. Leibniz held the eternal truths to depend on God’s intellect (*Theodicy*, 184), and so also divorced necessity and independence.

3 Divine necessity and the ontological argument

Some writers (for example, Penelhum 1971: 183-4) nearly equate (GN) with the claim that there is a sound ontological argument for God’s existence (see God, arguments for the existence of §§2-3). In this they follow Spinoza: ‘God is substance, which necessarily exists, i.e. to whose nature it pertains to exist, or (what is the same) from whose definition it follows that He exists’ (*Ethics* I, 19).

But there could be a sound ontological argument even if (GN) were false. Some such arguments (including Anselm’s in *Proslogion* 2) end in contingent propositions asserting God’s existence. An ontological argument is an a priori existence-proof. Descartes’ *Cogito* may try to prove a priori that a contingent being exists. If the *Cogito* does, it is not therefore absurd. In Kaplan-style indexical logics, ‘I exist’ is both contingent and an analytic or logical truth; there are also such truths in systems of modal logic employing actuality-operators (see Zalta 1988). One can hold both that it is provable a priori or even broadly logically necessary that a certain property is exemplified (as when mathematicians prove that there exist numbers with certain properties) and that the item having that property exists contingently (as on the theory that numbers are sets of sets of concrete things).

Conversely, even if (GN) is true, there might be no sound ontological argument: if (as Gödel reminds us) not every necessary truth is provable, perhaps ‘God exists’ is not. Some who take it that (GN) is true only if there is a sound ontological argument for God’s existence assume that if ‘God exists’ is necessary, ‘God does not exist’ is or entails a contradiction. But this is debatable. Arguably, both

(IO) there can be an immovable object, and
(IF) there can be an irresistible force

are necessarily true if true at all. At most one is true: if nothing can resist a certain force, the supposed immovable object cannot, and so is not after all immovable. But neither (IO) nor (IF) seems to entail a contradiction.

4 Objections to divine necessity

Some philosophers (for example, Findlay 1955) argue that:

(3) All necessary truths are true by convention.
(4) If (GN) is true, ‘God exists’ is necessarily true.
(5) So if (GN) is true, ‘God exists’ is true by convention.
(6) Merely conventional truths do not assert real facts.
(7) So if (GN) is true, ‘God exists’ asserts no real fact.

Findlay thinks (GN) a conceptual truth. So having argued for (7), he infers that ‘God exists’ asserts no real fact -

that is, that God does not really exist. Theists might instead take (3)-(7) as a *reductio* of (GN). But (3) no longer seems patently true. Further, even if conventionalism is true, (5) is not. On conventionalism, if (GN) is true, our ways of using words determine the modality of ‘God exists’ and so determine whether (GN) is true. It doesn’t follow that our usage determines whether God *exists*. Perhaps we have the power Anselm thought God has, to make God’s existence necessary but not to make God exist.

If ‘God exists’ is necessary but conventionally so, (GN) entails ‘God exists’ without explaining or grounding it. If this is the case, one has to ask why our conventions have the good luck to affirm as necessary what really does exist. But such questions are not unanswerable. (For instance, if there is a God, he might want us to believe (GN), and might design us to do so.) If (GN) is conventionally true, (GN) is not a good reason to affirm that God exists; until we find on other grounds that God exists, we have no guarantee that we do not have the wrong convention. But this does not even entail giving up all forms of ontological argument, so it has little significance.

Some philosophers (for example, Edwards 1976) argue that:

(8) if (GN) is true, ‘God exists’ is analytic, or true due to its meaning.
(9) If ‘God exists’ is analytic, it is true because its subject-concept (God) contains its predicate-concept (existence).
(10) So if ‘God exists’ is analytic, existence is a predicate.
(11) Existence is not a predicate (as Kant argued).
(12) So (GN) is false.

(8)-(11) may even imply that (GN) is conceptually incoherent, since it assigns ‘exists’ to the wrong semantic category. Edwards rests (8) on the theory that broadly logical necessity is analyticity. But this theory is now widely rejected. Rather, a proposition is broadly logically necessary if and only if true in all broadly logically possible worlds. Some such propositions seem not to be analytic - for example, that everything green has some spatial property (Adams 1987: 45-6). Some might argue, following Anselm, that ‘God exists’ is true in all possible worlds because whatever ‘possible worlds’ are, they depend on God for their existence (see Morris and Menzel 1986).

A different sort of objection to (GN) arises because (GN) implies that ‘something exists’ is necessarily true. We seem able to conceive (in some sense) there being nothing at all. Being able to conceive (in some sense) that this is true is defeasible evidence that it is possible. If possibly there is nothing, ‘something exists’ is not necessarily true. Still, there are many sorts of conceivability. They do not all have equal weight as evidence for possibility. Adams (1971: 285-6) suggests that conceiving that *P* is greater evidence that *P* is possible the closer it is to imagining the actual experiences one would have were *P* true. One cannot do this for ‘nothing exists’, for if nothing existed, there would be no experiences, or minds to have them.

Necessary truth and convention

Necessary truths have always seemed problematic, particularly to empiricists and other naturalistically-minded philosophers. Our knowledge here is a priori - grounded in appeals to what we can imagine or conceive (or can prove on that basis) - which seems hard to reconcile with such truths being factual, short of appealing to some peculiar faculty of a priori intuition. And what mysterious extra feature do necessary truths possess which makes their falsity impossible? Conventionalism about necessity claims that necessary truths obtain by virtue of rules of language, such as that 'vixen' means the same as 'female fox'. Because such rules govern our descriptions of all cases - including counterfactual or imagined ones - they generate necessary truths ('All vixens are foxes'), and our a priori knowledge is just knowledge of word meaning. Opponents of conventionalism argue that conventions cannot ground necessary truths, particularly in logic, and have also challenged the notion of analyticity (truth by virtue of meaning). More recent claims that some necessary truths are a posteriori have also fuelled opposition to conventionalism.

1 The linguistic theory of necessity

Many of the clearest necessary truths - such as 'Squares are rectangles' - seem simply to reflect the meaning of the words involved: we need not postulate some metaphysical essence of squareness which the necessity of 'Squares are rectangles' reflects. Thus, the position common to conventionalists is that necessary truths are explained by conventional rules of language, rather than a mind-independent modal structure of the world. For this reason, the general conventionalist position has often been called the linguistic theory of necessity (or, of the a priori). This was the dominant view about necessity from the 1930s-50s, particularly under the influence of logical positivism (see Logical positivism). Drawing largely upon claims they found in Wittgenstein's *Tractatus* (see below), the positivists rejected Kant's claim that there are synthetic a priori truths, trumpeting the slogan 'The a priori is analytic' (see Analyticity). What exactly analyticity was - beyond, in some way, truth by virtue of the meanings of words - was not entirely clear, which gave rise to different versions of the linguistic theory. But for most, conventionalism itself was beyond doubt and, apart from the few explicitly engaged in trying to spell out just how conventions explained necessity, most writers used different ways of articulating the view ('All necessary truths are tautologies', 'Necessity simply reflects linguistic rules') interchangeably simply to invoke the linguistic theory.

An early expression of conventionalism is found in Locke's proposal that all essences are merely nominal - they simply reflect the meaning of the subject term, as in 'Gold is a metal'. In this, Locke meant to contradict the then-received view that essences are determined by a mind-independent sorting of things. Similarly, he says essences 'are made by the mind' (1689: III.vi.26), and since 'kinds' - or in Locke's terms, 'sorts' - are the kinds they are because of their essences, Locke says the sorts themselves are 'the Workmanship of the Understanding' (1689: III.vi.12) (see Locke, J. §4). This well exemplifies the metaphysically deflationary thrust of conventionalism.

While there are various conventionalist views, they agree negatively both in their suspicion of appeals to imagination and conceivability as sources of factual knowledge, and in their finding the notion of necessary facts - and a distinction between essential and accidental properties - rather mysterious (see Essentialism). On the positive side, they agree in seeing appeals to imagination and conceivability as appeals to what we would *say* in various imagined situations, which they see as a way to find out what rules of language we are implicitly employing.

The version of conventionalism presented in Wittgenstein's *Tractatus* focuses on the notion of 'tautology', that is, truth-functional compound statements, such as 'If it is raining, then it is raining', which are true for all assignments of truth-values to the propositions from which they are built (1922: 4.46). Wittgenstein argues that tautologies say nothing about the world; rather, the symbols, given their meanings, themselves determine the truth of such statements (1922: 4.461-4661, 5.142). He claims that all truths of logic are tautologies (1922: 6.1-112) and seems to hold this for all a priori truths (for example, 1922: 5.134, 5.634). There are necessary truths which are not truths of logic, such as 'All bachelors are unmarried'. However, since 'bachelor' means 'unmarried man', the statement, when analysed, says, 'All unmarried men are unmarried', the form of which is 'Whatever is *F* and *G* is *F*', which is a tautology. One problem this version of conventionalism faced was accounting for necessary truths such as 'Nothing can be simultaneously both red and green all over' - for it is hard to see how to assign meanings to 'red'

and 'green' whereby this can be reduced to a tautology.

Other conventionalists have concentrated more on the general idea that truths such as 'All squares are rectangles' express rules of language. Their 'truth by convention' could perhaps serve as a model for all necessary truths. One version of this idea was that 'Necessarily, all squares are rectangles' simply means 'It is a rule of language that "square" applies to something only if "rectangle" also applies'; A.J. Ayer wrote that necessary propositions 'simply record our determination to use words in a certain fashion' (1936: 84). This view was regularly criticized for identifying necessary a priori truths with contingent empirical statements about a language or its speakers. A subtler variant was that one should not really speak of necessary truths at all - what look to be assertions are really, covertly, prescriptions ('Do not apply "square" to anything you would not apply "rectangle" to') or perhaps decisions of some sort. One problem here is that necessary statements can stand in logical relations, can figure essentially in truth-functional compounds, and so on, which seems to require that they have truth-values, unlike prescriptions. The most common version of this view is simply that the rule determines the truth of the sentence; given the rule, nothing can count as a square but not a rectangle. This view does not require that all rules have the form of definitions which allow us, via substitution, to reduce all necessary truths to syntactical tautologies; a rule prohibiting the simultaneous use of 'red all over' and 'green all over' to an object need not be rooted in a full, necessary-and-sufficient-conditions style definition of some constituent term (see Carnap 1952).

While many attacks on conventionalism only properly address particular versions, certain problems challenge any sweeping conventionalism. By the late 1950s, not only was conventionalism no longer dogma but, to many, seemed simply mistaken. One central problem concerns the fact that whether some convention obtains is always a contingent matter - but how can something which is contingent make anything necessary? For instance, even conventionalists (generally) acknowledge that different conventions would not affect the necessity of: if if *p* then *q*, and *p*, then *q*. But if different conventions would not change what is necessary, how can the conventions be responsible? Different conventions can change which proposition is expressed - but not the necessity of the proposition actually expressed. Another general problem concerns the idea that logical truths obtain by convention. The conventionalist wants to say that, given certain rules, it follows that certain statements are true (and necessary). But 'follows' is an expression of necessitation. Quine (1966) and others argue that in order to derive the truths of logic from conventions, one must apply logical rules - one must presuppose logic in order to derive logic. Additionally, attacks on the analytic/synthetic distinction, particularly vivid in arguments put forward by Putnam (1975) that apparently analytic truths are actually revisable empirical claims ('Cats are animals'), cast further doubt on the analytic explanation of necessity. If there are no analytic truths, they cannot explain necessity (see Analyticity).

2 Necessity a posteriori

In *Naming and Necessity* (1980), Saul Kripke argued that the supposition that all necessary truths are a priori is mistaken. His examples included empirical identity statements, such as 'Hesperus is Phosphorus', statements of material origin, such as 'This lectern was originally made of (a particular piece of) wood' and statements of kind essence and identity, such as 'Gold has atomic number 79'. Since these are not a priori, they cannot simply be true by convention, and if conventionalism was already on the wane, Kripke's examples, and similar ones from Putnam (1975), seemed to kill it decisively. Because these truths are not logically necessary, but are still necessary absolutely, they are sometimes called 'metaphysically necessary'.

However, it has been noted that even if these necessary truths are not true by convention, they may still owe their necessity to convention (see Coppock 1984, Sidelle 1989). The arguments for proposed necessary a posteriori truths each involve commitment to some general principle, for instance, that if a material object originates in bit of matter *M*, then it essentially originates in *M*. These principles - in so far as the arguments for the necessities are plausible - are plausibly a priori, for the arguments rest on the familiar appeals to what we can imagine, or would be willing to say. The conventionalist proposal, then, is that these general principles are analytic, and that while these conventions do not determine which non-modal statements are true (what bit of matter something did originate in), they are responsible for these truths being necessary (the principle determines that nothing with a different origin can count as this object). So conventionalism does not require that all necessary truths are *true* by convention, but only that this is why they are necessary.

Neckham, Alexander (1157-1217)

Alexander Neckham is one of the leading thinkers in the English appropriation of the new science made available during the twelfth century. His best known writings, especially De naturis rerum (On the Natures of Things), show a prodigious acquaintance with natural history. Neckham was most concerned, however, that the study of the natural world be made to serve the purposes of theology. He thus strove not only to draw moral lessons from nature, but to apply to theological method the doctrines of the new logic, especially Aristotle's Topics. While Neckham cannot be said to have mastered the texts that were flooding into the Latin West, he certainly did realize the challenges and the possibilities that they offered to inherited theologies.

Alexander Neckham (also Neckam or Nequam) displays in his writings that zeal for new learning that characterizes the 'renaissance' of the twelfth century in Latin-speaking schools of western Europe. Neckham lived out his life in these schools. He studied and then taught in Paris from about 1175 to 1182, where his subjects were the liberal arts and theology, with some law and more medicine. Neckham remarks that he was a student of the school on the Petit-Pont, and his writings reflect the doctrines of the school's most famous master, Adam of Petit-Pont. From Paris, Neckham returned to England to teach in the grammar schools of Dunstable and St Albans. Not long after 1190 he was in the schools at Oxford, which were just then beginning to reorganize themselves in ways that would make them into a university. There are many references in Neckham's writing to Scholastic techniques, such as the exercise of the *disputatio* or disputed question, and there survives a set of theological questions that he determined. The appropriation of newer techniques was also perfectly compatible with the cultivation of older ones. Neckham established himself at Oxford as an important preacher and as the author of a commentary on the Athanasian creed. About 1200, he withdrew to the monastery of Augustinian canons in Cirencester, where he was elected abbot in 1213. Neckham's most extended and important works were written at the monastery. He died there, as abbot, in 1217.

Neckham is best known to historians of philosophy as a student of natural philosophy. Part of this reputation is due to his being the recipient of lavish praise in a contemporary treatise, Alfred of Shareshill's *De motu cordis (On the Motion of the Heart)*. Alfred wrote the treatise at Neckham's prompting while the latter was still at Oxford. However, Neckham's reputation as a student of natural philosophy is due more substantially to several of his own works, especially *De naturis rerum (On the Natures of Things)* and *De laudibus divinae sapientiae (Praise of Divine Wisdom)*.

De naturis rerum takes the form of an immense prologue to a commentary on Ecclesiastes. The relation of 'prologue' and body is not entirely clear, especially since *De naturis rerum* itself begins as a commentary on the account of creation in Genesis. Whatever Alexander's exact motive, the work quickly enough becomes something like an encyclopedia of moralized natural philosophy. It is loosely organized around the four elements of ancient physics - fire, air, water, earth - but the range of erudition is enormous. In 272 chapters over two books, Neckham rehearses most of the natural history known to him, from problems in astronomy, through the hydrodynamics of fountains and the properties of precious stones, to the behaviour of animals, wild and domestic. Although much of the material is taken from ancient sources, such as Pliny, Neckham frequently adds information or anecdote of his own. More importantly, he regularly reads the facts he recites so as to yield a moral lesson. Indeed, the whole of *De naturis rerum* ends with a sustained attack on human vices, thus making a bridge to the reading of Ecclesiastes.

Neckham returned to these topics in a metrical compendium, his *De laudibus divinae sapientiae*. It too is ordered around the four elements, but ranges widely. In it the reader finds Neckham reciting catalogues of the stars and of Europe's main rivers, as well as descriptions of jewels, herbs and trees and the liberal arts. Still not satisfied with his comprehensiveness, Neckham returned to natural history again in a *Suppletio defectuum (Remedy of Defects)* appended to *De laudibus*, where he offers new descriptions of animals and their habits.

The ordering of natural knowledge to theology, always a concern, seems to have occupied Neckham increasingly. He tries to show the right ordering of them in his last great work, the *Speculum speculationum (Mirror of Speculations)*. The work is announced and begun as a refutation of the heresies of the Cathars. It is in fact, and from the beginning, organized roughly along the lines of Peter Lombard's *Sentences* (see Lombard, P.). It expands on the topics of the *Sentences*, increasing the number of arguments and the length of their analysis. Neckham does

much, for example, to bring in the still relatively little known works of Anselm of Canterbury. Of course, some of his erudition is drawn from theological *florilegia*, anthologies of excerpts drawn from the Christian Bible, the Church Fathers or medieval theologians of the Latin tradition. Neckham also knows and uses the Platonic and Neoplatonic texts popular among philosophical writers earlier in the century: Plato's *Timaeus* with Calcidius's commentary, Boethius with his medieval commentators, and at least some of Thierry of Chartres, William of Conches and Bernard Silvestris (see Bernard of Tours; Platonism, medieval).

What is more striking, because it is much newer, is Neckham's appropriation for theology of the 'new logic' and newly translated works by Aristotle (see Aristotelianism, medieval). Certainly Neckham knew the logical works well. In constructing his dialectical theology, he makes much use of Aristotle's *Topics*, so becoming one of the first theologians to capitalize on this recently rediscovered text. His relation to other Aristotelian works is more difficult to discern. Neckham refers by name to *On the Soul*, *Metaphysics* and *Nicomachean Ethics*, and he quotes without reference from *On the Heaven and the Earth*. Such early access to these works suggests that Neckham may have brought them back with him from the continent. Equally striking is an implicit citation of Avicenna's *On the Soul*, one of the new wave of Arabic works just finding their way into Latin and into the northern schools. To say that Neckham mentions or sometimes uses these texts is not to say that he has mastered them. On the contrary, he stands at the beginning of what will be a very long effort to read and then to understand the texts that were pouring into Latin so rapidly from both Greek and Arabic (see Translators).

List of works

Neckham, Alexander (before 1182?) *De nominibus utensilium (On the Names of Utensils)*, ed. A. Scheler, 'Trois traités de lexicographie latine du XIIe et due XIIIe siècle', *Jahrbuch für romanische und englische Literatur 7*, 1866: 58-74, 155-73. (An elementary survey of technical terms from arts and crafts as encountered in ordinary use; modelled after a work by Adam Parvipontanus.)

Neckham, Alexander (before 1182?) *Corrogationes Promethei (Collections of Prometheus, that is, of one who teaches rudimentary arts)*, excerpts ed. P. Meyer, 'Notice sur les Corrogationes Promethei d'Alexandre Neckham', *Notices et extraits des Manuscrits de la Bibliothèque Nationale* 35 (2), 1896: 641-2.(An introduction to grammatical theory, based on teaching in the Paris schools; incomplete.)

Neckham, Alexander (1194-1204) *De naturis rerum (On the Natures of Things)*, ed. T. Wright, Rolls Series, London: Longman, Green, Longman, Roberts and Green, 1863; Books 3-4 never printed.(A comprehensive survey of knowledge about the natural world; the work is the first two parts of a five-part commentary on Ecclesiastes, the remainder of which has never been printed.)

Neckham, Alexander (*c*.1213) *De laudibus divinae sapientiae (Praise of Divine Wisdom)*, ed. T. Wright, Rolls Series, London: Longman, Green, Longman, Roberts and Green, 1863. (A metrical rehearsal of the order of nature.)

Neckham, Alexander (1216-7) *Suppletio defectuum (Remedy of Defects)*, excerpts ed. H. Walther, 'Zu den kleineren Gedichten des Alexander Neckham', *Mittellateinisches Jahrbuch* 2, 1965: 111-21.(A correction and supplement to the *De naturis rerum*; incomplete.)

Neckham, Alexander (1201?-17) *Speculum speculationum (Mirror of Speculations)*, ed. R.M. Thomson, Oxford: Oxford University Press, 1988.(Treatment of all the major topics in Christian theology, with dialectical analysis and ample use of the pertinent authoritative texts; incomplete.)

Needs and interests

To have an interest in something is to have a stake in how that thing goes. Needs can be thought of as interests instrumental to a specified purpose, as an artist will need paint, or as general essential interests, like the needs associated with physical survival. Both needs and interests can be contrasted with wants, in being more objectively assessable. A concrete specification of needs and interests is better done by means of a list than by a criterion stipulated in terms of goods that would be chosen in a hypothetical situation. The concept of need can be used to justify a claim to economic resources, even though it only states a minimal demand. However, when total resources will not meet all needs, it is necessary to work with the principle of the equal consideration of interests rather than that of needs, as in the case where health care needs may outstrip available resources. The concept of interests can be misused in defence of authoritarian political systems, but does not have to be used in this way. Although citizens may have an interest in performing their duty, it is likely that there will always be a continuing conflict between duty and interests in politics.

1 The concepts of needs and interests

As concepts, needs and interests are closely related, although not identical. If I say that I need to go to the dentist, I will normally be taken to imply that dental treatment would be in my interest. However, not everything in a person's interest is a need. For example, securing tax allowances may be in the interests of the rich, but it is not something that they need.

It would be difficult to imagine political, legal, moral and practical discussion without the concept of interests. Political parties advance certain interests, legal institutions arbitrate between interests, moral systems restrain the scope of self-interest and practical reason considers how actions will promote interests. Indeed, on one theory of action, agents are moved only by their own interests.

It is possible to distinguish between something being in someone's interest and someone taking an interest in something. I may take an interest in something purely for the sake of curiosity, for example the performance of my local sports team, without my interests being affected by that performance, as they would be if I had a financial stake in their results. However, there are many aspects of life where the two notions coalesce. For example, parents will have an interest in their child's career success if that affects their own household income, but typically they will also take an interest in it, in the sense of being personally concerned.

What then are interests? In a well-known definition John Locke (1689: 15) defined interests as 'life, liberty, health, and indolency of body; and the possession of outward things, such as money, lands, houses, furniture and the like'. This definition takes the form of a list of things that are thought to be the generalized means, in the form of personal conditions and external possessions, to some supposed human good. Feinberg (1984) has expressed the matter by saying that to have an interest in something is to have a stake in it, and to have a stake in *X* is to stand to lose or gain depending on what happens to *X*.

Needs may be regarded as a subset of interests, namely those interests that are in some sense essential or necessary to one's affairs. As necessary conditions, needs can be stipulated in a weak or strong sense. In the weak sense, they are simply the conditions required to achieve any goal or general aim. In this sense, an artist will need paints and brushes in order to work. In such cases the claims of need depend upon an evaluation of the end state to which the need is instrumental.

In the strong sense, needs are the conditions required to achieve some basic goal like survival. In this case needs designate those items necessary to having any purposes at all, or to avoid serious harm. These may thus be called vital interests, their claims being correspondingly higher than instrumental needs.

Both needs and interests may be contrasted with wants. I may not want to go to the dentist, but I may need to, because my health will suffer if I do not. One way of putting this point is to note a logical difference in the inferences that can be drawn from sentences concerned with wants and those concerned with needs. Wants are always characterized from the point of view of those with the wants, and in consequences their full implications may remain obscure to their possessor. For example, I may want to take the fastest train to my destination, but not know that I want to take the 1300, because I do not know that it is the fastest. Thus, one cannot validly infer from

my wanting *X* that I want *Y*, which is identical with *X*, unless I am also known to identify *X* and *Y*. By contrast, if I need *X* it can be validly inferred that I need *Y* identical to *X*, independently of my own state of mind.

A similar point holds in respect of interests. There is therefore an objectivity about needs and interests that there is not about wants. The contrast is not absolute, and the concept of interest can sometimes come close to a more subjectivist notion of welfare or want-satisfaction, since how people conceptualize their interest or balance conflicting interests can vary (see Welfare §1). So, we cannot say that the religious who pursue their spiritual development at the cost of poverty are acting against their own interests. But that is partly because people can have an interest in the conditions of their own personal development, and this can clash with material interests.

Since interests need to be balanced in this way, can we state a general criterion for identifying how this would be done? One suggestion is to identify interests thus balanced with the informed hypothetical choices that agents might make. On this account, the balance of interests represented by policy *X* is more in my overall interests than that produced by policy *Y*, were I to prefer the results of *X* to those of *Y* when I experience them both. However, unless the hypothetical choice occurs, it would seem that the only way we could know what choices someone would make is to have a sense of what their interests already involve, so that the prediction of choice is grounded in our understanding of needs and interests and not vice versa. In this sense, interests are logically prior to choice.

2 Needs, interests and economic distribution

The concept of need is frequently linked to questions of economic justice. For example, modern health and welfare services are often said to be based on the principle of meeting need irrespective of the ability to pay. But can the principle of need be used in this way to underscore a claim for resources?

Of the two meanings of need that we have so far distinguished, it is clear that the sense relevant is the strong one stated in terms of means to basic goals like survival. Distribution according to need thus means no more than that people should be assured of the means of subsistence and survival.

It may be urged that as a principle of distribution the appeal to needs is too undemanding, since the means of survival are widely available in modern societies, and therefore economic justice should be concerned with broader claims of justice, for example that there should be an equal consideration of interests above the minimum needed for mere survival (see Justice).

However, the proposal to dispense with a principle of need in economic matters has to be treated with some caution. The notion of survival is not itself clear-cut, and it can include the means to secure self-respect in society. Adam Smith (1776) pointed out that, although Romans did without a linen shirt, even the poorest labourer in Smith's day would be ashamed to appear in public without one. Thus, what is necessary to survival has a cultural, as well as a material, component which varies from society to society, so that needs will expand over time as an economy grows.

Moreover, in the context of claims for the international redistribution of resources, the appeal of the principle of need is strong, since on a global scale not all are assured of the means of survival even in the physical sense. In this context, a basic-needs strategy of economic development would entail some significant redistribution, and the principle would be neither empty nor without force (see Justice, international).

Yet the principle of the equal consideration of interests may come to supplant the needs principle in some circumstances. For example, distribution of care according to need has been a traditional principle in medicine. Yet modern technology makes it possible to meet an increasing range of medical needs, but only at impossibly high cost. Where resources are inadequate to meet the sum of needs, certain needs will have to remain unmet, and an alternative principle found for rationing resources, for example that all are entitled to an equal consideration of their health interests.

3 Interests in politics

The concept of interests in politics has historically been associated with the democratic idea that government should act in the interests of the governed, rather than acting, say, for an abstract ideal like national glory or spiritual purity. However, the appeal to interests can also be ambiguous in democratic terms, since a government

may well appeal to the idea of interests as a way of ignoring popular sentiment and opinion. Exploiting the logical space opened up by the distinction between wants on the one side and needs or interests on the other, a government might claim to know what is in the interest of people better than the people itself. A strong notion of interests might therefore seem to lend itself to a paternalist or authoritarian notion of government.

The danger of paternalist or authoritarian government arising from this substitution of elite judgement for the opinion of the people has been widely feared. However, it is difficult to dispense with the idea that there may be some occasions when governments should act according to the interests of citizens rather than being responsive merely to expressed wants. For example, when people underinsure themselves against age dependency or ill health, the government might properly compel individuals to act in their own long-term interests by instituting compulsory pension and health insurance schemes. Indeed, even the most liberal government will not allow individuals to sell themselves into slavery (see Paternalism).

We can distinguish between people wanting a policy and people wanting the results of a policy. One way in which it is possible to guard against the paternalist or authoritarian tendencies implicit in the idea that governments should act in the interests of the people is to say that these interests should be related to the policy results that people were seeking. Thus, if citizens value economic security, requiring compulsory savings to achieve this may well be justified as it would not be justified to impose puritan policies restricting individual liberty of action when spiritual purity was desired only by a few.

4 Interests and moral powers

So far we have considered interests as personal conditions and external possessions determining how individuals fare. But Rawls (1993) has proposed the concept of ‘higher-order interests’ (see Rawls, J. §1). Citizens with a conception of their own good and a sense of justice also have these higher-order interests in the development and exercise of these two powers. On this conception, then, instead of thinking of interests as the basis of claims on resources, we are to think of them as motivations to cooperative social action, making it in the interests of citizens to observe principles of justice.

To extend the notion of interest in this way has certain advantages, not least in understanding how citizens might have an interest in acting justly. Conflicts between the duties of justice and acting on one’s own self-interest would, in effect, become conflicts within one’s own sense of self-interest. To adopt this construction would have the disadvantage, however, of running contrary to the common observation that acting justly may often involve acting against one’s self-interest. Moreover, as a statement of philosophical psychology, it is hard to see how it is empirically supported.

Yet, even if interests are often opposed to duty, individuals can think of their interests as being wider than simply their own personal concerns and can identify with the interests of their community. In this sense, the idea of moral powers may point to a socializing of interests that is essential to any workable conception of justice.

Negative facts in classical Indian philosophy

Like their European counterparts, the philosophers of classical India were interested in the problem of negative facts. A negative fact may be thought of, at the outset at least, as a state of affairs that corresponds to a negative statement, such as 'Mr Smith is not in this room.' The question that perplexed the philosophers of India was: How does someone, say Ms Jones, know that Mr Smith is not in the room? There are essentially four possible metaphysical positions to account for what it is that Ms Jones knows when, after entering a room, she comes to know that her friend is not present there. Each of the positions has been adopted and defended by certain classical Indian philosophers. On the one hand, some take the absence of the friend from the room as a brute, negative fact. Of these, some hold knowledge of this fact to be perceptual, while others hold it to be inferential. On the other hand, some hold that the absence of the friend from the room has no real ontic status at all, and believe that what there really is in the situation is just the sum of all the things present in the office. These latter philosophers hold that knowledge of one's friend's absence is just knowledge of what is present, though some believe the knowledge results from perception, while others believe it to result from inference. These four positions were maintained by, respectively, the Nyāya *philosopher Jayanta, the* Mīmāṃsā *philosophers Kumārila Bhaṭṭa and Prabhākara, and the Buddhist Dharmakīrti.*

1 Introduction to the problem

Negative facts have perplexed Western philosophers ever since the time of Plato. But the philosophers of Europe and America have not been the only philosophers to have been perplexed by them; classical Indian philosophers too have pondered their nature. The problem, as raised by classical Indian philosophers, is easy enough to state. Suppose that someone, say Ms Jones, enters a room and her friend, Mr Smith, is not there. How does Ms Jones know that Mr Smith is not there? One obvious answer, tendered by the classical Indian philosopher Kumārila Bhaṭṭa, is that Ms Jones fails to perceive Mr Smith (*Ślokavārttika* 9.11). While this answer has the ring of common sense, there are reasons to baulk at accepting it. To begin with, perception and inference are, in one sense, faculties or cognitive capabilities, whereas nonapprehension (*anupalabdhi*), the act of failing to perceive something, is not. There is, however, a more important reason to abandon the view that nonapprehension of something is a means of knowledge of its absence - something may be present yet not be perceived. Suppose that when Ms Jones enters a room, it is night, the lights are out, and the room is completely dark. Under these conditions, she would fail to see Mr Smith, even though he might very well be present.

Four main responses to the problem of negative facts can be discerned in classical Indian thought: that they are correctly analysed as straightforward positive facts known through inference; that there are real negative facts but that they can only be known through inference; that negative knowledge comes directly from perception of positive presences; and that we directly perceive real negative facts. Below, arguments for and against these positions are stated, although no attempt is made to track down their metaphysical origins and the related arguments. Rather, the exposition is confined to the authors whose treatments of the issue are the earliest ones which are both complete and sustained. They are those of Dharmakīrti (*c*.600-60), a Buddhist; of the followers of Kumārila Bhaṭṭa (*c*.620-80), an adherent of Mīmāṃsā; of Prabhākara (*c*.650-720), another adherent of Mīmāṃsā; and of Jayanta (*fl.* 890), an adherent of Nyāya.

2 The view of Dharmakīrti

The first classical Indian philosopher known to have understood and addressed the problem which confronts the view of Kumārila Bhaṭṭa was his older contemporary, Dharmakīrti. According to Dharmakīrti, both in his *Nyāyabindu (Drop of Logic*; 2.12-) and his *Pramāṇavārttika (Commentary on Valid Cognition*; 3.3-6 and commentary), one knows something when one correctly reports, having entered a room under the right conditions, that one's friend is absent from it; but what one knows is not a negative fact and is not known by perception. Rather, what one knows is a simple (positive) fact and it is known by inference.

A form of inference which comes to mind here is one advocated by Raphael Demos (1917) in an article in which he criticized Bertrand Russell's espousal of the existence of negative facts in his *The Philosophy of Logical Atomism*. Demos suggested that knowledge of absences is based on the relation of inconsistency between, on the one hand, the simple (positive) fact one observes upon, say, entering a room, and, on the other hand, the state of

affairs of one’s friend’s presence.

To be sure, Dharmakīrti holds that the relation of inconsistency plays a role in many inferences which warrant one’s claim to know some allegedly negative facts. For example, he holds that from the presence of heat one can infer an absence of cold, since heat and cold are inconsistent (with respect to the same locus). But it is not his view that inference based on the relation of inconsistency plays a role in the case where Ms Jones enters a room and comes to know that her friend is not there. In such a case, Dharmakīrti maintains, Ms Jones reasons as follows: the causal conditions of perception known are such that, if her friend were present in the room, she would see him; she does not see him; therefore, he is not present. The inference is counterfactual (see Gillon 1986 for further discussion).

Does Dharmakīrti’s counterfactual inference obviate the need to invoke the existence of absences? It seems not. Suppose, for example, one knows that one’s friend is absent from a room. This can be symbolized as $\neg p$. According to Dharmakīrti, one knows this because one has inferred it from two premises which one already knew: first, the counterfactual conditional that if one’s friend were present in the room, then one would know that the friend were present there; and second, the fact that one does not know that the friend is present in the room. These facts can be symbolized as $p \rightarrow Kp$ and $\neg Kp$ (where ‘*K*’ denotes the epistemic operator corresponding to the English ‘*a* knows that’ and ‘ $\rightarrow$’ denotes the connective for counterfactual conditionals). But this gives rise to a dilemma: how does one know that one does not know that one’s friend is present in the room? In other words, how does one know that $\neg Kp$? On the one hand, if Dharmakīrti holds that one perceives that one does not know that one’s friend is present in the room, that is to say, that one perceives that $\neg Kp$, then Dharmakīrti accepts thereby not only the existence of negative facts, in this case, negative mental facts, but also their perceptibility, both of which he wants to deny. On the other hand, if Dharmakīrti holds that one infers that one does not know that one’s friend is present in the room, that is to say, that one infers that $\neg Kp$, then there must be an inference to ground that claim, just as there is an inference to ground the initial claim that one’s friend is not present in the room, that is, $\neg p$. An infinite regress of inferences becomes inescapable, despite Dharmakīrti’s protestations to the contrary (see *Pramāṇavārttika* 3.3 and commentary).

3 The view of Kumārila Bhaṭṭa’s followers

A different position regarding negative facts and knowledge of them is the one adopted by the followers of Kumārila Bhaṭṭa. Though they maintained, unlike Dharmakīrti, that there are negative facts, they none the less seem to have adopted his view that knowledge in such cases is derived only from counterfactual inferences. These philosophers, unlike Dharmakīrti, but like most other classical Indian philosophers, considered counterfactual reasoning (*tarka*) neither as a form of inference (*anumāna*) nor, in general, as a standard means of knowledge (*pramāṇa*). The case of counterfactual reasoning yielding knowledge of negative facts was set aside by them as a means of knowledge unto itself, called ‘nonapprehension’ (*anupalabdhi*). Their view, of course, suffers from the very same dilemma just raised with respect to Dharmakīrti’s view, namely the dilemma of having either to concede the perception of some negative facts or to accept, for any negative fact said to be known, an infinite regress of inferences of negative facts.

4 The view of Prabhākara

A younger contemporary of Kumārila Bhaṭṭa, Prabhākara, who shared many of his philosophical assumptions, adopted the view that what one knows when, upon entering a room, one comes to know that one’s friend is absent from the room is some visually perceived, positive fact, that is, some presence. But what would be the plausible candidate for such a presence? Well, suppose Ms Jones’ friend, Mr Smith, usually sits in some chair in the room. According to Prabhākara, the pertinent presence would be the presence of the chair Mr Smith usually sits in. What else could there be to the absence of Mr Smith from his chair than the presence of the chair he usually sits in? After all, as Gerd Buchdahl (1961: 176-7) has observed in considering this problem in the Western philosophical tradition, one needs to draw only one picture to draw a picture either of the chair Mr Smith usually sits in or of the same chair without him in it. Yet Prabhākara’s metaphysical opponents were sceptical of the validity of this retort: they pointed out that if Mr Smith’s absence were identical with the presence of the chair he usually sits in, then any time Ms Jones perceives the chair, including the times when Mr Smith is in it, she should know that Mr Smith is absent. This, according to the opponents, is patently absurd.

Prabhākara apparently sought to extricate himself from this objection by denying that the presence of Mr Smith in the chair he usually sits in is the same as the presence of his chair without him in it: in the former case there are two presences, that of Mr Smith and that of the chair he usually sits in; but in the latter there is only one, namely that of the chair Mr Smith usually sits in. Opponents suspected that this distinction cannot be made without directly or indirectly relying on an assumption of the existence of absences; for, as they pointed out, to distinguish the presence of one's friend in his chair from the presence of only his chair requires the use of such expressions as 'only' (*eva*) or 'merely' (*mātra*), which are implicitly negative expressions, since to say that there is only one presence is to say that there is at least one presence and there is no more than one presence.

Prabhākara faced another objection. How could he account for the fact that, when one sees simply one's friend's chair, what one comes to know is the friend's absence and not one of the infinity of other absences which are also then present? One reply is to maintain that there is a difference between what one sees and what one remarks upon, and that this difference obtains equally in cases of perception of what are unquestionably presences as well as in cases of perception of what are allegedly absences. For the very same reason that when one looks at a desk and remarks that there is a pad of paper on it, but fails to remark that there is a pencil on it, one remarks on Mr Smith's absence from a chair he usually sits in, but one does not remark on the absence of, say, an elephant from it.

5 The view of Jayanta

An alternative to Prabhākara's position is one advocated by Jayanta. He agrees with Prabhākara that perception is the relevant means for Ms Jones to know that Mr Smith is absent from a room, but disagrees with him that all that is relevant to Ms Jones' knowledge of Mr Smith's absence is her perception of some presence. Rather, Jayanta holds that absences are brute facts unto themselves and that Mr Smith's absence in the case described is known through perception. Like others of the same school (Nyāya), he thought of perception as a causal process, the linchpin of which is contact between the object of perception and the appropriate sense organ. Thus, for example, in the tactile perception of the pencil in one's hand, the key causal link is the contact of the organ, the skin, with the pencil. This view of perception, however, raised an immediate problem: if contact between an object of perception and the appropriate sense organ is the key link in the causal process of perception, how can there be perception of absences, for surely it is absurd to think of any sense organ as coming into contact with an absence?

Jayanta's response to this objection was to revise the definition of sense perception: he restricted the above definition to the perception of positive facts and provided a special clause to account for perception of negative facts. According to Jayanta, this move was not *ad hoc*; and at least within his overall metaphysical framework there are independent grounds for its adoption, for he believed that, though universals do not come into contact with the sense organs, they none the less can be perceived. In general, something is perceived just in case it is a physical thing suited to a sense organ and in contact with it, or it is a universal inhering in a physical thing and both the universal and the physical thing are suited to the sense organ, or it is an absence related to a place and both the absence and the place are suited to the sense organ.

Gillon, 'Introduction to Dharmakīrti's Theory of Inference as Presented in *Pramāṇavārttika Svopajñavṛtti* 1-10', *Journal of Indian Philosophy* 19: 1-73.(A very difficult and important work on logic and metaphysics in the Indian philosophical tradition. The Gnoli edition provides

critical notes as well as the Sanskrit text.)

Dharmakīrti (*c*.600-60) *Nyāyabindu*, ed. D. Malvania, *Paṇḍita Durveka Miśra's Dharmottarapradīpa*, *Being a Sub-commentary on Dharmottara's Nyāyabinduṭīkā*, *a Commentary on Dharmakīrti's Nyāyabindu*, Tibetan Sanskrit Works Series 2, Patna: Kashiprasad Jayaswal Research Institute, 1955; 2nd edn, 1971; trans. T. Stcherbatsky, in *Buddhist Logic*, vol. 2, New York: Dover Publications, 1962.(A clear but all too concise compendium of its author's views on logic and metaphysics.)

Gillon, B.S. (1986) 'Dharmakīrti and his Theory of Inference', in B.K. Matilal and R.D. Evans (eds) *Buddhist Logic and Epistemology*, Dordrecht: Reidel, 77-87.(A self-contained explanation of how Dharmakīrti treats knowledge of absences as a form of inference.)

Gillon, B.S. (1997) 'Negative Facts and Knowledge of Negative Facts', in P. Bilmoria and J.N. Mohanty (eds) *Relativism, Suffering, and Beyond: Essays in Memory of Bimal K. Matilal*, Delhi: Oxford University Press, 1969, 128-49.(A contemporary philosophical treatment of the issue, which takes into account both Western and Indian views.)

Jayanta (*c*.890) *Nyāyamañjarī*, ed. K.S. Varadacharya, *Nyāyamañjarī of Jayanta Bhaṭṭa with Ṭippaṇi - Nyāyasaurabha by the Editor*, Mysore: The Oriental Research Institute, University of Mysore, 1969, 2 vols; trans. J.V. Bhattacharya, *Nyāya-Mañjarī: The Compendium of Indian Speculative Logic*, New Delhi: Motilal Banarsidass, 1978, 102-32.(This work provides a clear and comprehensive overview of the issues of classical Indian philosophy. The last fifth of the first āhnika (pages 102-33 of the English translation, 130-67 of the Sanskrit edition) provides a useful summary of views on the knowledge of absences.)

Kumārila Bhaṭṭa (*c*.620-80) *Ślokavārttika*, ed. G.Ś. Musalgaonkar, *Mīmāṃsā Darśana Ślokavārttika of Kumārilabhaṭṭa with Śābarabhāṣya, the Commentary Nyāyaratnakara and Notes*, New Delhi: Bharatiya Vidya Prakashan, 1979, 2 vols; trans. G. Jhā, *Śloka-vārttika: Translated from the Original Sanskrit with Extracts from the Commentaries of Sucarita Miśra (The Kāśikā) and Pārthasārathi Miśra (Nyāyaratnākara)*, Bibliotheca Indica 146, Calcutta: Asiatic Society of Bengal, 1907; repr. New Delhi: Sri Satguru Publications, 1983.(This work is the fundamental text of the school of Mīmāṃsā (founded by Kumārila Bhaṭṭa.)

Russell, B. (1918) *The Philosophy of Logical Atomism*, ed. D. Pears, La Salle, IL: Open Court, 1985.(This important philosophical work contains a passage which is a rejoinder to Demos' proposed treatment of negative facts.)

Stcherbatsky, T. (1930) *Buddhist Logic*, Bibiotheca Buddhica 26, Leningrad: The Academy of Sciences of the USSR, 2 vols; repr. New York: Dover Publications, 1962. (This important yet tendentious and often unclear introduction to Buddhist logic contains a usable translation of Dharmakīrti's *Nyāyabindu*.)

Negative theology

*The term 'negative theology' refers to theologies which regard negative statements as primary in expressing our knowledge of God, contrasted with 'positive theologies' giving primary emphasis to positive statements. The distinction was developed within Muslim, Jewish and Christian theism. If the negative way (*via negativa*) is taken to its limits, two questions arise: first, whether one may speak of God equally well in impersonal as in personal terms (blurring the distinction between theism and, say, the philosophical Hinduism of Śaōkara); and second, whether it leads ultimately to rejecting any ultimate being or subject at all (blurring the distinction between theism and, say, the atheism of Mahāyāna* Buddhism*). However, within their original theistic context, positive and negative statements about God are interdependent, the second indispensably qualifying the first, the negative statements taken alone useless.*

Negative qualifications on positive statements attributing so-called 'perfections' to God - for example, existence, life, goodness, knowledge, love or active power ('strength') - are obviously necessary if God is unimaginable. If his presence is always of his whole being and life all at once, in each place in space and time, he must be non-spatial and non-temporal in being and nature, and clearly he must be unimaginable. However, his supposed 'simplicity' and 'infinity' imply that he is much more radically outside the reach of understanding or 'comprehension', imposing the negative way at a deeper level than mere unimaginability. This unimaginability and incomprehensibility are key to theistic accounts of prayer and the mystical life.

1 The negative way in older Christian tradition

Within Christian theology, the negative way (called 'apophatic' from Greek) has two very different roles. First, if God is unimaginable and incomprehensible, this negative way is integral to any right understanding within theology as a 'theoretical' ('speculative') study considering models and using discourse and argument to assist understanding of God and his plan for creation (so far as this understanding is linguistically expressible). Second, the negative way is essential to the use of the intellect as directed practically towards union with God, that is, to the theology of spirituality and what Lossky (1957) calls 'mystical' theology. However, such theology seems to depend on positive statements about God, first for its context - some particular teaching and liturgy - enabling the mind to be directed in attention and love towards God and no other, and second for its verbal expression. This being directed towards God is typified when the mind is moved towards a loving, non-conceptual knowledge of God, setting aside images and concepts; this is illustrated in the mystical writings of Gregory of Nyssa and the poetry and commentaries of John of the Cross, their teaching being 'practical' in the sense explained by Jacques Maritain (1959). This love, whether realized in mystical prayer or as the unseen root of more active forms of life and prayer, is essentially directed to God, one who is holy or 'wholly other' (Otto 1917), not to any finite object of which we might form an image, or grasp or comprehend in nature.

The pre-Christian idea of a name as a means of control over what is named, bringing it within reach of human science and manipulation, is echoed in the negative emphasis both in the Old Testament and the Greek Fathers, who said that God 'has no name', or is 'ineffable'. This negative perspective was reinforced by Exodus 33: 18-23, which represents Moses as unable to see God's face, but only his back, and is echoed in the Gospels: 'no man has seen God at any time' (John 1: 18). Basil speaks of God as descending to us in his operations and John of Damascus suggests three possible etymologies deriving the word *theos* (God) from an operation. From these suggestions and the fifth-century writings of Pseudo-Dionysius, later Eastern tradition developed the idea that we never say anything positive of God's 'essence' (God as he is in himself), but only about his 'uncreated energies' - a development especially marked in Gregory Palamas and Eastern councils in 1351 and 1357. Latin tradition never accepted any distinction between God's essence and uncreated energies, but insisted that when we refer to God's existence, life, goodness, greatness, love, strength and suchlike, we refer to God's essence, that is, to God as he is in himself ('*substantialiter*' in Aquinas); however, it still maintained a parallel negative bent, which is highlighted in the Fourth Lateran Council's statement in 1215 that 'between Creator and creature no similarity can be expressed without including a greater dissimilarity' (Tanner 1990: 232).

2 Negative theology in Thomas Aquinas

The classic Western solution of the problem was presented by Thomas Aquinas (*Summa theologiae* Ia, qq.1-13).

He explains that we speak of things according to the way in which we know them (q.13, a.1), and speak of God as 'we know him from created things as their cause (*principium*), by way of excellence and by negation (*remotio*)'. In this traditional phraseology, he was not referring to three distinct kinds of statement about God, but to how we are to understand positive statements attributing 'perfections' to God, for example, existence, life, goodness, knowledge, love and active power. In each case, God as cause or principle of creatures possessed the perfection beforehand in a more eminent way, and not in any of the finite ways in which the perfection concerned is exemplified in creatures (see God, concepts of §§1-6).

Any such approach, allowing certain terms to be applied both to God and to creatures, but in different ways, absolutely involves some flexibility in our use of these terms - Aquinas saw this flexibility in the possibility of middle ways between terms being used 'equivocally' and being used 'univocally' (in identical senses in different cases). 'Analogy' was his blanket term covering all such middle ways.

For Aquinas, the words we use to signify things belonging to the essence of a particular sort of creature express things stateable in its definition, whereas what they signify in God's case cannot be contained in a definition. A definition makes the thing defined the object of human comprehension in some particular science. In Aquinas' conception, no kind of theology can yield comprehension (meaning master grasp, rather than loose understanding), and there is no science of God in the sense applicable to other sciences. Theology proper can only arise because by revelation God gives us some participation in his own knowledge of himself and of the way to him, participation in a style appropriate to human nature, and therefore using human language and concepts, including metaphors (*Summa theologiae* Ia, q.1). Aquinas has no conception of any self-contained natural theology, but only of a general metaphysics reaching some theological conclusions which, despite their limited character, give metaphysics some fuller integration (see Aquinas, T. §§9, 14).

In Aquinas' view, we can know the relevant statements about God to be true, some through philosophical reflection, and these and others through revelation, but we cannot comprehend God or the way he exists, lives, knows, loves and is good, or his mode of relation or action towards creatures, and so we have no comprehension or imagination of what makes these statements true. Terms for such 'perfections' apply truly to God in their proper or literal sense - it would, for example, be absurd to suppose that the cause of other things existing existed in a less real or proper sense than its effects. None of these most general positive terms has one definition even with regard to all creatures, each being used of different kinds of creature according to different definitions, or - in modern parlance - according to different criteria. Each such term is used of different types of thing 'analogically'. Although we learn to use them of creatures first, as applying in this or that way or respect, they apply unrestrictedly only to God. With regard to God, they have no 'scientific' definition. (The special term 'God' applies only to God and presents different but related problems: 'God' is the name of a nature, grammatically parallel to terms such as 'angel', 'animal', 'human being' and 'horse', and is not a formal or category term such as 'substance' or 'quality'; but still neither 'God' nor any other term applying to God alone has any real definition.)
